Water quality control measures implemented

- Restoration of the Kis-Balaton wetlands (21+54 km², second stage is still under construction)
- Development of the sewer system (>90% sewer connection ratio in shoreline municipalities)
- Introduction of phosphorus precipitation and stricter effluent P standards at sewer treatment plants
- Diversion of treated STP effluents to other watersheds
- Banning of liquid manure technologies at livestock breeding farms on the watershed
- Reduction of the use of fertilizers on the watershed (a “spontaneous measure” due to re-privatization of land)

Change of total phosphorus load to Lake Balaton

Water quality trends

Keszthely basin (Basin 1) having the poorest water quality
Improving trend except the 2000 – 2003 period

Chlorophyll-a concentrations in the Keszthely basin

Water quality trend in the four basins

Improving trend except the 2000 – 2003 period

Comparison of maximum chlorophyll-a concentrations and trophic states in the four basins

Effect of water exchange on salt content

The four-basin completely mixed tanks model for Lake Balaton

Property	Unit	Basin1 Keszthely	Basin2 Szigliget	Basin3 Balatonszemes	Basin4 Siófok	Total
Area	km ²	36.3	145.1	187.4	219.7	588.5
Average Depth	m	2.36	2.97	3.34	3.81	3.36
Volume	million m ³	86	431	626	836	1978

Conceptual scheme of the model with sediment interaction

P1 = Dissolved inorganic phosphorous,
P2 = Algal phosphorous,
P3 = Detrital phosphorous,
P4 = Sediment available phosphorus
B = Algal biomass

One blue-green algae species is considered (*C. raciborskii*)

Wind induced sediment resuspension in Lake Balaton

Mathematical model:

- mass balances for the state variables,
- daily time step,
- 4 completely mixed tanks
- 20 nonlinear differential equations

Suspended sediment concentration is calculated separately with the wind induced resuspension model of Wake (2003)

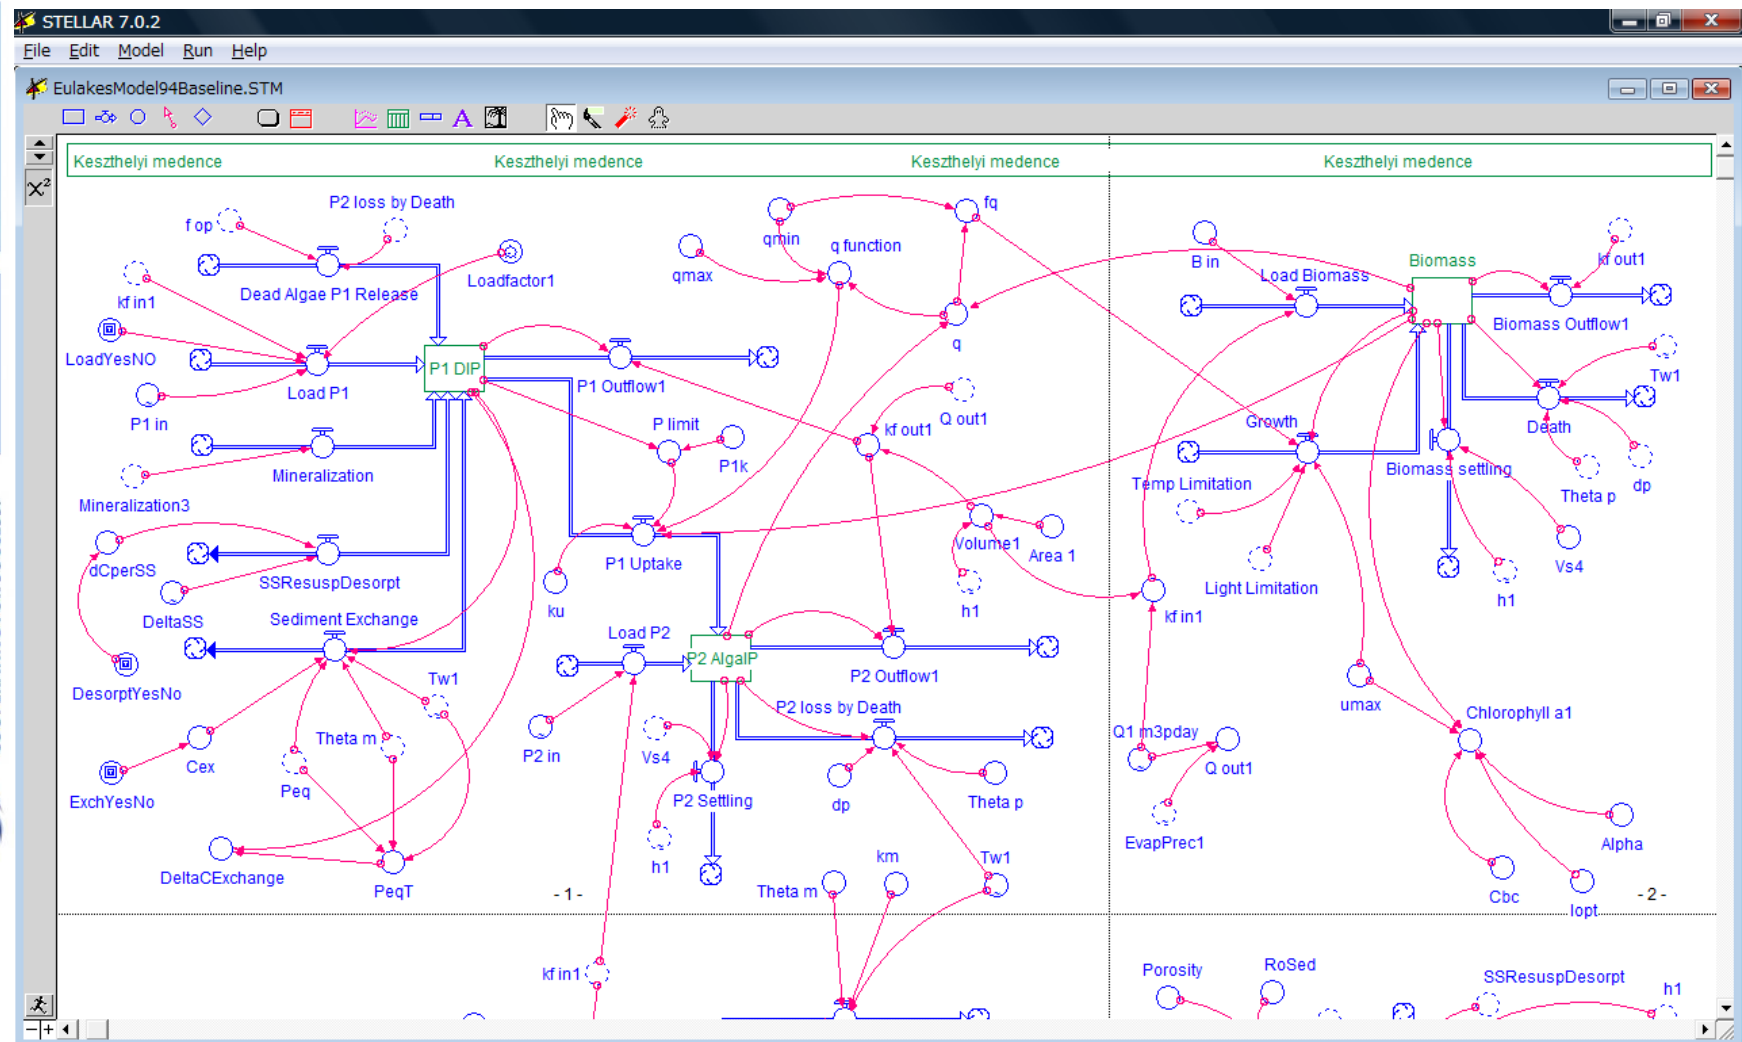

Two climate scenarios (B1, A1b)

covering 80 years with 20 year time steps

Two phosphorus load scenarios

with 25% and 50% load reduction

Results of model calculations I. with A1b climate regional scenario

Conclusions

EUROPEAN UNION
EUROPEAN REGIONAL
DEVELOPMENT FUND

CENTRAL
EUROPE
COOPERATING FOR SUCCESS.

- The model calculations show that the summer average chl-a concentrations are expected to increase considerably with climate change in case of both climate scenarios
- The summer maximum chlorophyll-a concentrations also increase but to a lesser extent
- A1b scenario resulted in slightly larger increases both in summer averages and maximums
- A 50% external P load reduction can compensate the climate effects up to about year 2035
- After 2055, the adverse impacts of climate change overrides the effects of load reduction
- Ambitious phosphorus load reduction efforts should be continued at Lake Balaton
- A more complex model taking into account other algae species and elements of the food web may result in higher reliability of predictions
