GWDG and ePIC

-  is a joint facility of Göttingen University and the Max Planck Society. It functions as the
 - data and IT competence center for the Max Planck Society, and as the
 - data center for the university.

-  builds a network of currently six strong scientific service providers signed a contract
 - to ensure a reliable and persistent identifier infrastructure
 - devoted to the needs of the research community at large.

- Mayor focus: the referability of data
 - with finer granularity
 - for sharing during the research process

- In RDA is the PID seen as the central component to mediate the access of *services* to *digital objects*
- Key feature for the central role of PIDs is the **resolution** and the **transparent presentation of metadata** by types
- This concept is also known as *digital object architecture (DOA)*

Policies and Profiles

- Policies of PID services describe the general way, how PIDs are maintained
 - deletion of PIDs
 - patterns for PID suffixes
 - enforce type profiles
- Profiles of PID services describe the allowed type pattern
 - lists for mandatory, optional and forbidden types

Types and PID Information Types (PIT)

- Types are a kind of metadata for digital objects,
 - rather structural and administrative than descriptive.
 - Types are used as **keys** for given **values**.
- Types can be stored inside the Persistent Identifier (PID) record.
 - This way one can operate with them independently from the digital object itself,
 - and similar to **mime types** as useful information before processing the data
- Such types are called **PID Information Types (PITs)**
- They are well referenced by a persistent identifier assigned to its definition (registration in a DTR).

Data Type Registries (DTR)

By registration of types in DTRs the properties of types become transparent (standards)

- Currently a couple of such DTRs exist,
 - based on *Cordra*², a software from an RDA WG outcome,
- The DTRs use a special vocabular for type specifications.
 - This vocabular is partly extended for different purposes.
- A process of federation of DTRs is ongoing,
 - which also requires a standard for the vocabular
- ePIC provides a DTR at <http://dtr.pidconsortium.eu/>
 - a type life cycle is introduced:
 - **in preparation, candidate, approved and deprecated**

Schemas for Types

- PID Information Types are used to prepare and enable the processing of digital objects.
- This requires high accuracy of the type value,
- at least syntactical correctness.
- Therefore a **schema** for each PIT is needed.
- Manual schema definition is cumbersome and errorprone.
- Automated processes would be of great help.

Hierarchies in Metadata

Example: geographic coordinate.

Hierarchical Type Definitions

- makes it easy to define new types
 - concept uses **basic PID info types** and **PID info types**
- in consequence:
 - semantics can be introduced easily by reuse of types under different names
 - `isPreviousVersionOf` and `isNextVersionOf` both refer to `ListOfHandles`
 - definition of complex types is simplified
 - possibility to derive automatically **schemas** for the type values
 - automated server side schema derivation implemented at ePIC DTR

Types vs. Linked Data

- An Example of a type: `isPreviousVersionOf` (see: `21.11104/3eaedeaced10be5805d2`).
 - Such a type is stored as key-value pair in the PID (*pid-do1*) of a digital object
 - as key-value pair consisting of the PID of the type (*pid-type*) and the PID of the previous version (*pid-do2*)

This gives a triple:

- *pid-do1 pid-type pid-do2*
- Digital-Object-1 `isNextVersionOf` Digital-Object-2

Thus one has a:

subject predicate object

relation with types, given by PID, as predicates.

RDF triples are *post web*:

- object is IRI/URI or literale
- subject and predicate are IRI/URI
 - literales are never subject or predicate
- IRI/URI are fuzzy endpoints with no persistancy
- the trust relation for the semantic of predicates is not explicit

Types are *post DOA (digital object architecture)*:

- object is PID or literale
- subject and predicate are PIDs
 - literales are never subject or predicate
- PIDs are persistent by construction
- DTRs build the trust relation for the semantic of predicates

- Handle REST API: only a list of all PIDs of a prefix

```
#> curl -u 'user:pwd' -X GET -H 'Content-Type:  
application/json'  
'http://hdl.handle.net/api/handles?prefix=21.11101'
```

- ePIC REST API:
maps **REST GET request string** to **SQL queries**
 - but this provides only a small subset of SQL queries
 - and has no specified SELECT part, matching PIDs are returned

ePIC Search

```
#> curl -u 'user:pwd' -X GET -H 'Content-Type:
application/json'
'http://demo.pidconsortium.eu/handles/21.11101/
?21.T11148/b497a0aad7d4c7179b4f=*Scive*
&21.T11148/1d8764d7dcfda12a864d=*Schwardmann*'
0000-0004-0F27-1
0000-0004-0F2E-A
0000-0004-107C-F
0000-0004-10CA-6
```

is internally by the ePIC API translated to

```
SELECT * FROM handles WHERE
(type=21.T11148/b497a0aad7d4c7179b4f AND data LIKE
'Scive') AND (type=21.T11148/1d8764d7dcfda12a864d
AND data LIKE 'Schwardmann')
```

Search in the RDF World

SPARQL-Queries:

- describe a subgraph and try to map that subgraph in the knowledge graph
- a query is intentional similar to SQL:

```
PREFIX foaf: <http://xmlns.com/foaf/0.1/>
SELECT ?name
       ?email
WHERE
{
  ?person a          foaf:Person .
  ?person foaf:name  ?name .
  ?person foaf:mbox  ?email .
}
```

Translation into the Handle World

PIDs, Types
and the
Semantic Web

Ulrich
Schwardmann

use *InfoTypes* as *predicates*:

- given InfoTypes *isPerson*, *hasName* and *hasEmailAddress* for a couple of PIDs:
 - the SPARQL query above returns names and emails of every *PID* with *isPerson*==True in the query scope (LHS/GHR/whatever)

Question for Handle services:

- provide more search functionality in the REST API or
- implement a SPARQL endpoint?
