Why

In the eWaterCycle II project we want the Hydrology modelling community to show off and run their own and colleagues models. Models can be exposed in a fancy web interface. On the press of a button, we generate Jupyter notebooks to quickly have a runnable model with basic Hydrograph plots.

How

The experiment launcher accepts a selection made in a visualization web application, next it will generate a notebook based on that selection and launch the notebook giving the user a URL where he/she can edit and run the notebook.

Other Jupyter extension by eWaterCycle team: JupyterLab THREDDS extension

Inject THREDDS or ESGF datasets into notebook cells as xarray, iris code snippets from inside JupyterLab environment
