## Abstract

- Alakol Lake is one of the largest hydrologically closed lake located in Balkash-Alakol River Basin in southeast Kazakhstan. Having a coastline approximately at 490 km Alakol Lake has faced multiple threats due to both natural and anthropogenic factors as a result of tectonic movements, geology and wind wave conditions, growing tourism activities, fishing and transport etc.
- The present study aims to investigate the coastline changes along Alakol Lake in Kazakhstan by using remote sensing data in particular scale-space images Landsat Thematic Mapper (TM), Enhanced Thematic Mapper (ETM+), Operational Land Imager and Thermal Infrared Sensor (OLI TIRS), Sentinel 2B images (S2B). Modified Normalized Difference Water Index was calculated to demonstrate the coastline changes along Alakol Lake between 1990 and 2018. Moreover, the monitoring and analysis of coastline dynamics is based on the main morphometric characteristics of Alakol including water surface area, coastline length, geomorphology of coast etc.
- Our results reveals that there is a continuous coastline shrink toward land, depending on the coast types. For example, in case of the accumulative coast (mainly northeast, north and northwest coasts) a coastline shrink toward land was from 200 to 900 m. As a result, vast areas of agricultural land were flooded and degraded wetlands. In case of the denudation coasts, a coastline shrink toward land was from 120 to 270 m between 1990 and 2018. This study demonstrates the importance of monitoring coastline dynamics, since it provides essential information for understanding the coastal response to contemporary nature and anthropogenic impacts.

## Research area

- Alakol Lake, located in the southeast of Eastern province of Kazakhstan (46°04'52" N, 81°45'51" E), with an area of 104x53.5 sq. km. The climate on Alakol Lake is a continental climate, with very cold snowy days in winter but very hot and dry weather in summer. Mean annual temperature and precipitation are 6.2-7.2°C and 152.9 mm. The maximum and average depth of the lake in 2018 was 54 and 22 m. The estimated living population in Alakol Lake was approximately 302.504 inhabitants. Anthropogenic activities in Alakol Lake region include settlements, irrigation systems, livestock, agriculture, tourism.

## Material and method

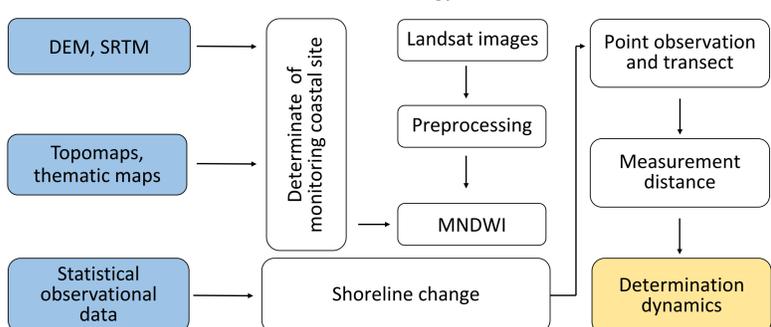

- The 30 m spatial resolution Landsat Thematic Mapper (TM), Enhanced Thematic Mapper (ETM+), Operational Land Imager and Thermal Infrared Sensor (OLI TIRS), Sentinel 2B images (S2B) were downloaded from the USGS catalog of the US Geological Survey via <https://earthexplorer.usgs.gov> for the period of 1990 - 2018.

No	Satellite	Satellite images	Acquisition date	Sensor	Pixel spacing (m)

- Morphometric conditions (slope, exposure, absolute heights) of the surface part of the coastal zone were analyzed via using Digital Elevation Model (DEM), Shuttle Radar Topography Mission (SRTM), medium-scale topographic map and thematic maps from National Atlas of the Republic of Kazakhstan.

- Modified Normalized Difference Water Index (MNDWI) is based on the different spectral bands - green and mid-infrared (MIR) bands. Band 2 (green) and band 5 (mid-infrared) spectral channels are used in Landsat 5 (TM) and 7 (ETM+):  $MDNWI = \frac{\text{band 2 (G)} - \text{band 5 (MIR)}}{\text{band 2 (G)} + \text{band 5 (MIR)}}$ . Band 3 (green) and band 6 (mid-infrared) are used in Landsat 8 (OLI TIRS):  $MDNWI = \frac{\text{band 3 (G)} - \text{band 6 (MIR)}}{\text{band 3 (G)} + \text{band 6 (MIR)}}$ .

### Overall flowchart and methodology of this research

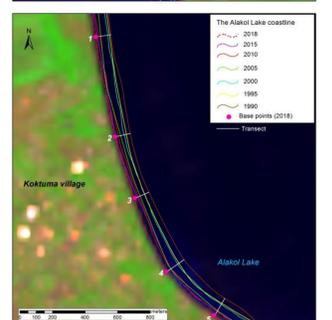

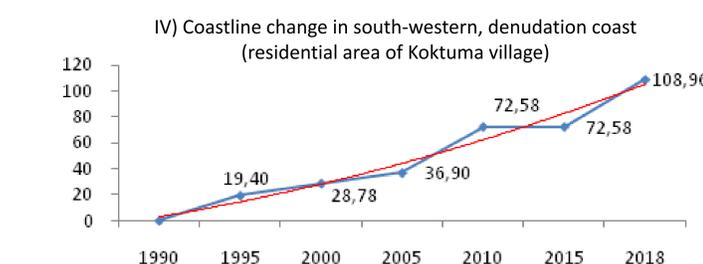

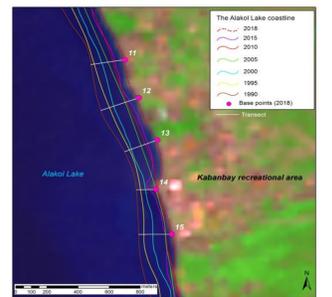

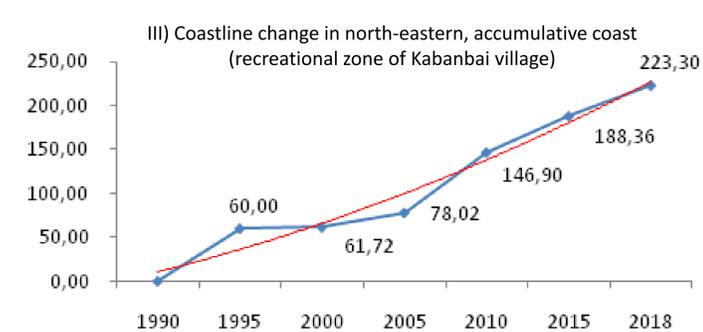

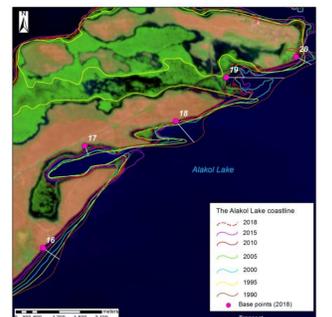

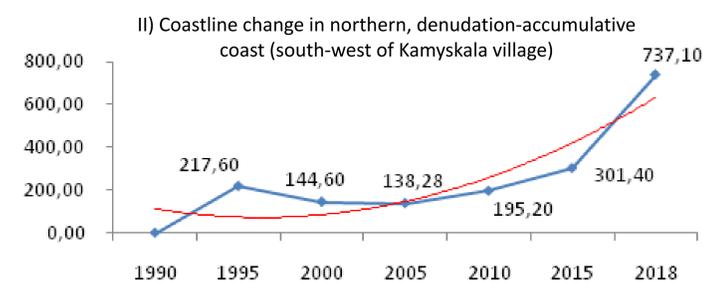

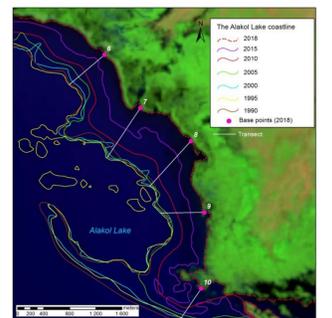

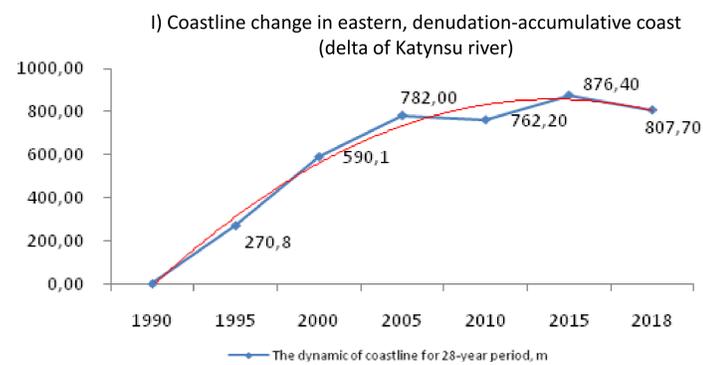

## Morphometric characteristics of Alakol coastal zone

## Coastline dynamics

- Monitoring site (I) in delta of Katynsu river: the coastline of the lake has moved forward toward land for about 1 km in some places. These are mainly low accumulative coasts, on which extensive wetlands are located;
- Monitoring site (II) in Kamyskala village: the shift of the lake's coastline is determined by an average of 120-180 m;
- Monitoring site (III) in Kabanbai village: over the 28-year period, the dynamics of the coastline toward land amounted to more than 200 m;
- Monitoring site (IV) in Kottuma village: the coastline has moved forward in the western direction, on average, for more than 130 m throughout the entire coast, the most drastic changes occurred during the period from 2000 to 2005.

- The water surface areas of Alakol Lake increased from 2912.3 to 3033.2 between 1990 and 2018; the length of the coastline increased from 422.1 km in 1990 to 427.3 in 1995; from 434.2 in 2005 to 489.6 in 2010; from 482.4 in 2015 to 517.2 km in 2018.
