

Changing Hydrologic Exchanges in a Warming World

Main author: *Kirsten Findell – GFDL*

Ruud van der Ent – TU Delft

What is the magnitude of each of these terms in the global hydrological cycle?

How will they change in a warming world?

We can address these questions with water tracking algorithms

- e.g., WAM-2layers, van der Ent et al. (2010 WRR, 2014 ESD)
- GFDL's ESM2G (Dunne et al., 2012, 2013)

Findell, K. L., Keys, P. W., van der Ent, R. J., Lintner, B. R., Berg, A. and Krasting, J. P.: Rising Temperatures Increase Importance of Oceanic Evaporation as a Source for Continental Precipitation, *Journal of Climate*, 32(22), 7713–7726, [dx.doi.org/10.1175/JCLI-D-19-0145.1](https://doi.org/10.1175/JCLI-D-19-0145.1), 2019.

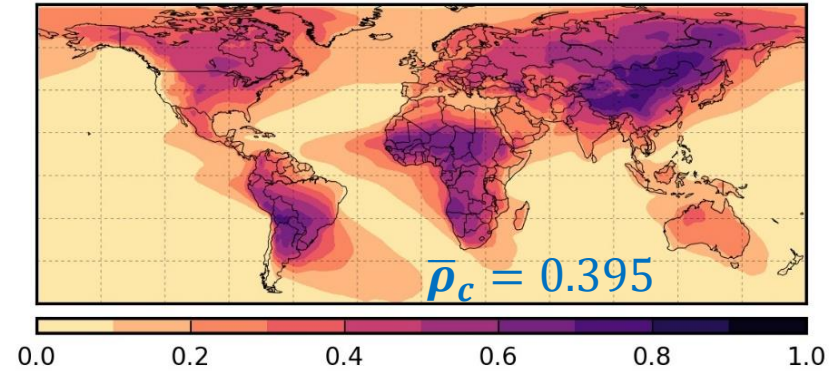

Precipitation tracked backwards

- The continental precipitation recycling ratio, ρ_c ,

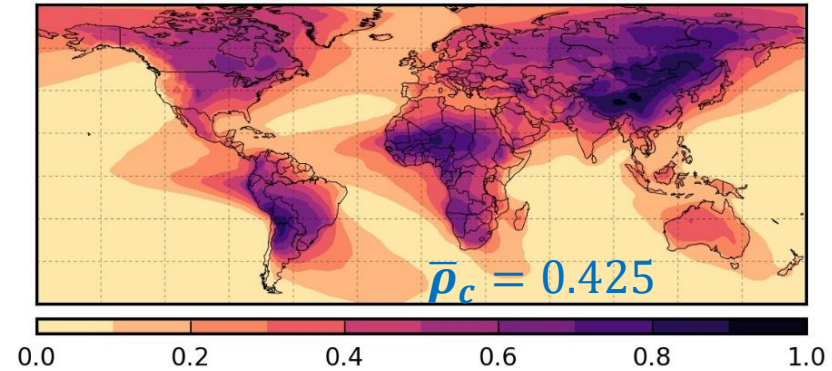

$$\rho_c(t, x, y) = \frac{P_c(t, x, y)}{P_c(t, x, y) + P_o(t, x, y)} = \frac{P_c(t, x, y)}{P_{TOT}(t, x, y)}$$

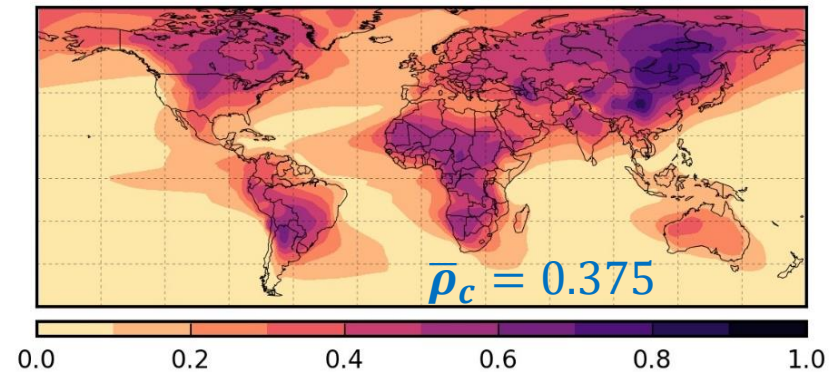

(b) ERA-I continental precipitation recycling ratio ρ_c

(d) MERRA continental precipitation recycling ratio ρ_c

(f) ESM2G End-20thC continental precip recycling ratio ρ_c

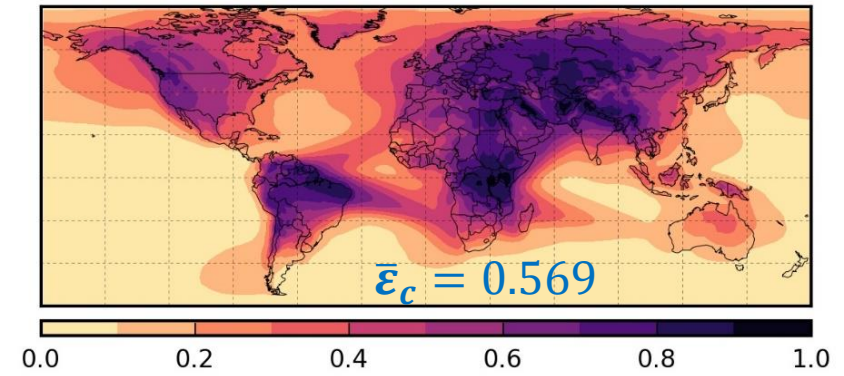

Evaporation tracked forwards

- The continental evaporation recycling ratio, ϵ_c ,

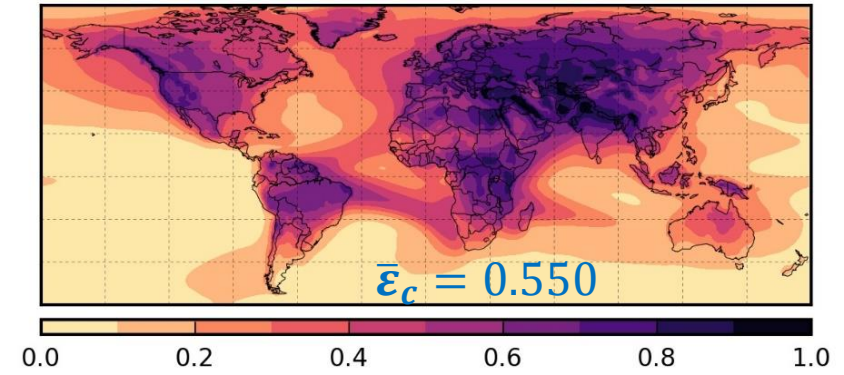

$$\epsilon_c(t, x, y) = \frac{E_c(t, x, y)}{E_c(t, x, y) + E_o(t, x, y)} = \frac{E_c(t, x, y)}{E_{TOT}(t, x, y)}$$

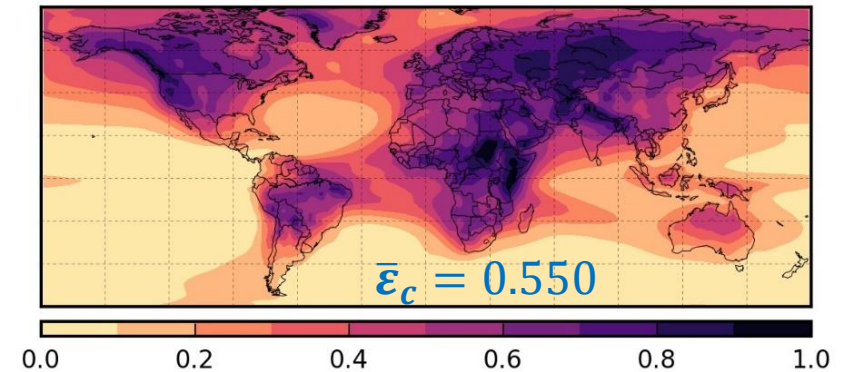

(a) ERA-I continental evaporation recycling ratio ϵ_c

(c) MERRA continental evaporation recycling ratio ϵ_c

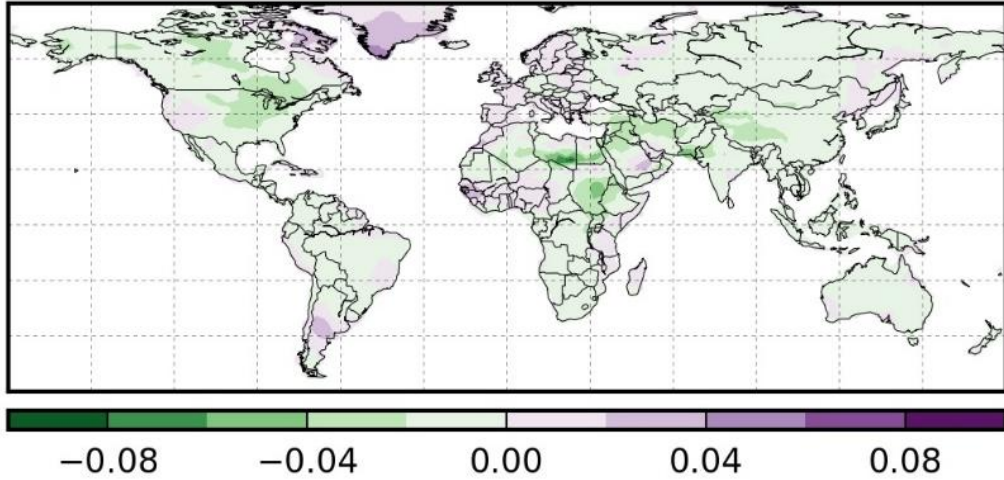

(e) ESM2G End-20thC continental evap recycling ratio ϵ_c

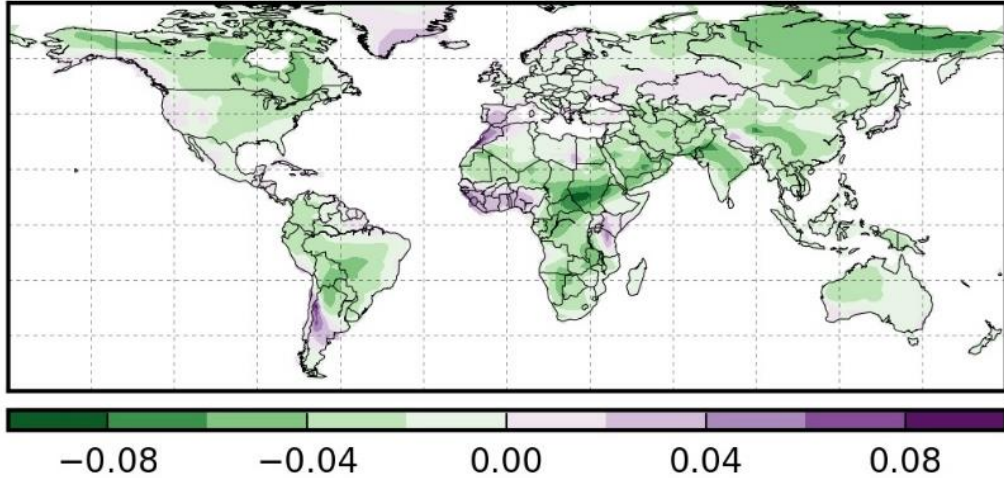

(b) End20thC - End19thC continental precip recycling ratio ρ_c

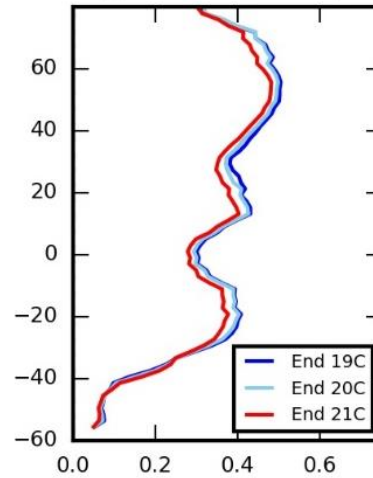

(d) End21stC - End20thC continental precip recycling ratio ρ_c

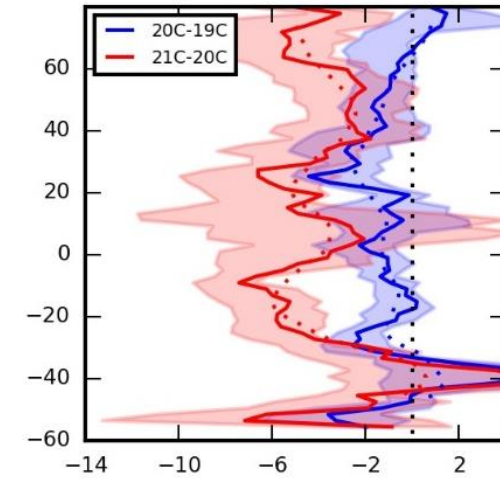

Continental moisture recycling decreases with warming

(g) Zonal mean ρ_c

(h) % change from earlier time period

With a simple prototype model, we can show that as long as $\Delta E_{ocean} > \Delta E_{land}$ as $\Delta T \uparrow$, then continental moisture recycling ratios must go down.

Soil moisture limitation on land, then, means that ρ_c must decrease in a warming world.

Changes in Hydrologic Exchanges

ESM2G's near-global (60°S-80°N) values in 1000 km³/yr

As global temperatures warm, both recycling ratios get smaller: the ocean imprint on continental hydrology gets bigger

Continental moisture recycling decreases by 2-3% with each degree of increase in global temperatures
