Reuse of extractive waste from an abandoned mine site: Case study of Campello Monti, Italy

Neha Mehta, Giovanna Antonella Dino, Iride Passarella,
Franco Ajmone-Marsan, Domenico Antonio De Luca

Date: 4 May - 8 May 2020

Study site: Campello Monti

Geographical location

Campello Monti is in Italian region of Piedmont.

Geological Setting

Mafic formation intruded by mantle peridotites.

Minerals:
Chalcopyrite,
pentlandite,
pyrrhotite

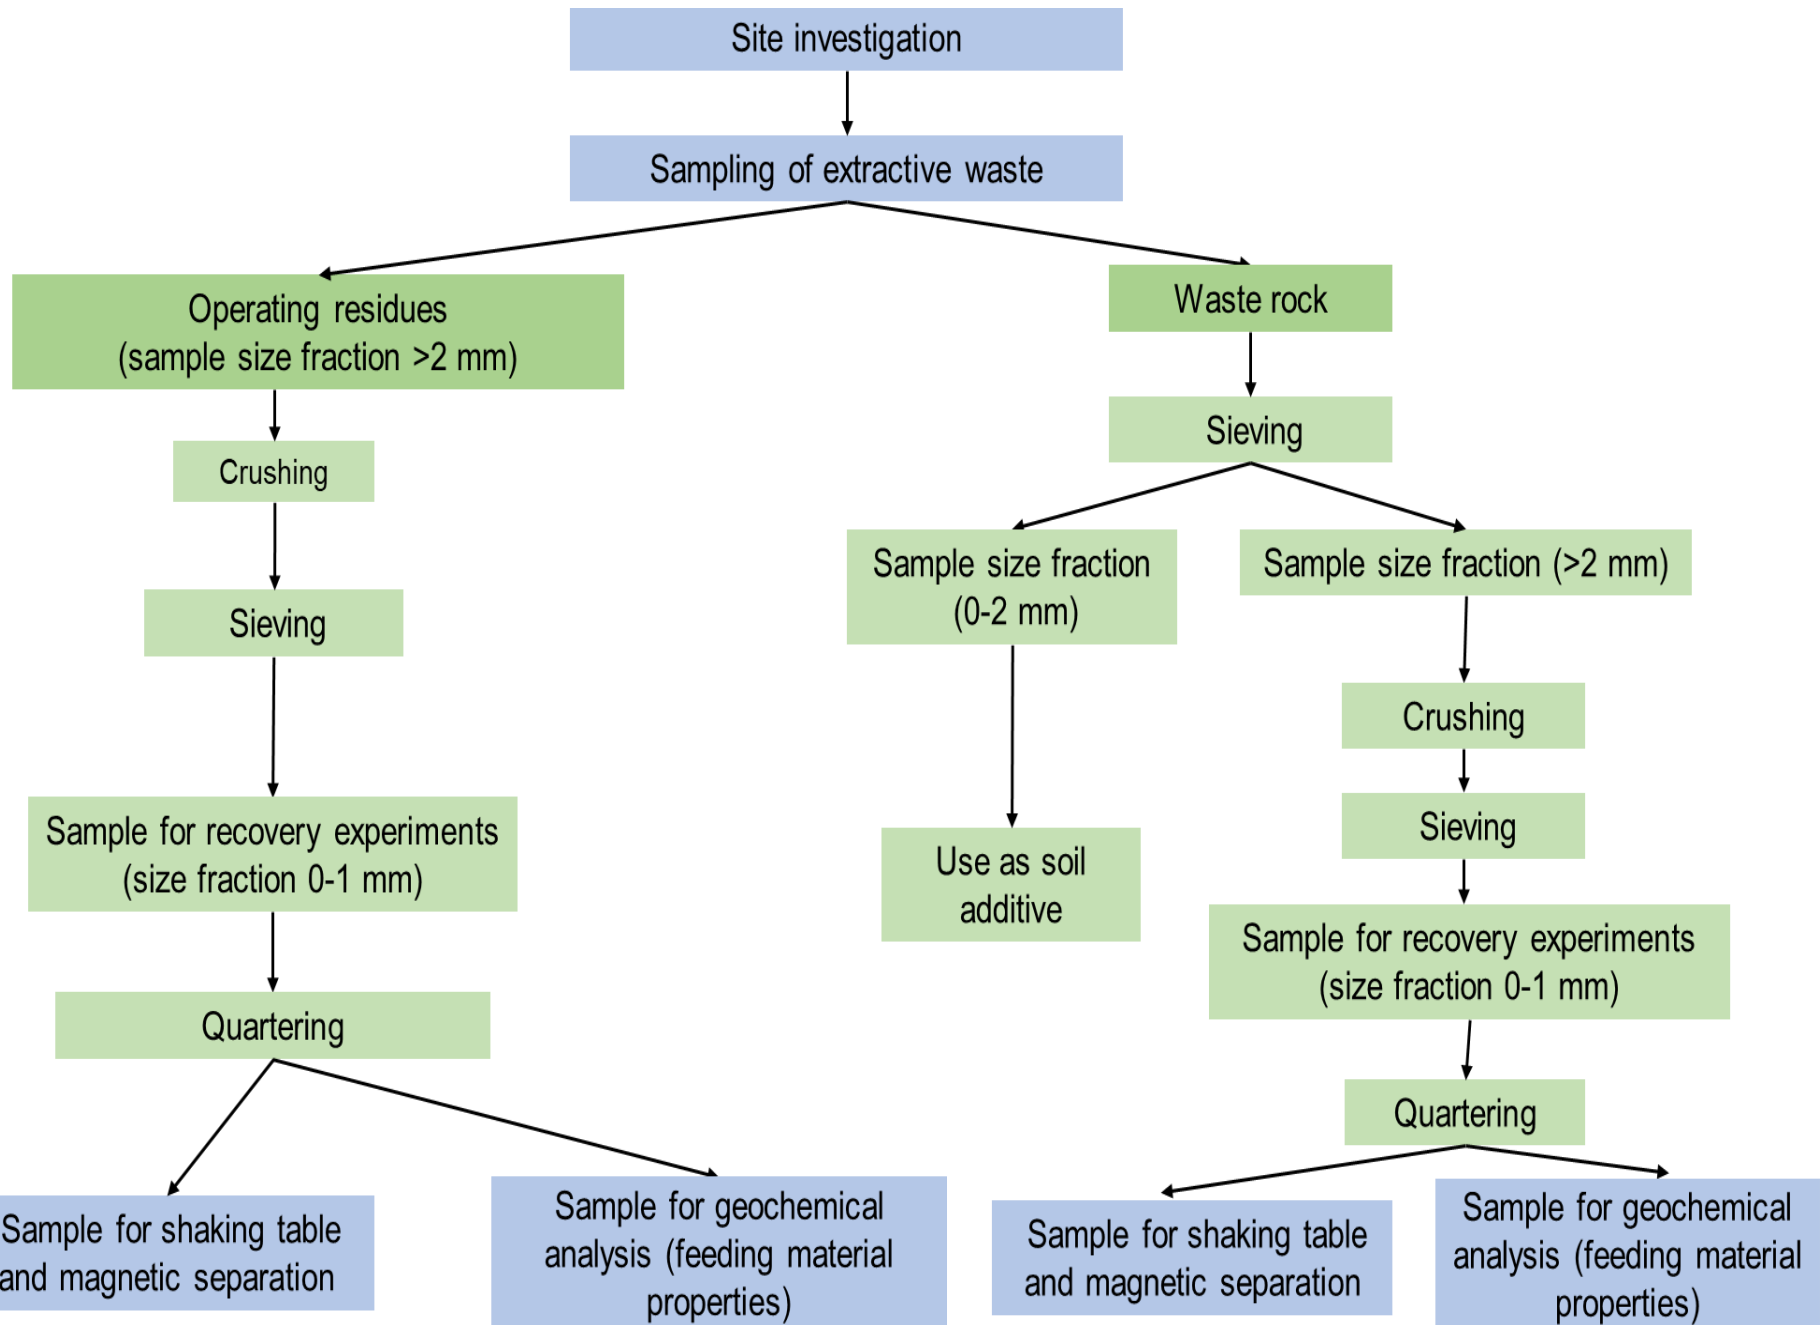

Exploitation activity

About fifteen small Fe-Ni-Cu-(Co) sulphide deposits occur. Nickel exploitation occurred from 1865 to 1943.

Sampling

In total 50 samples of **waste rock** and 31 samples of **operating residues** were collected

Sample preparation for reuse

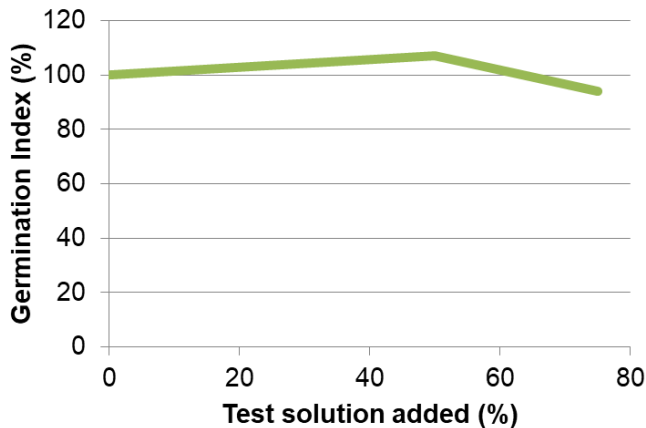

Reuse of fine fraction as soil additive

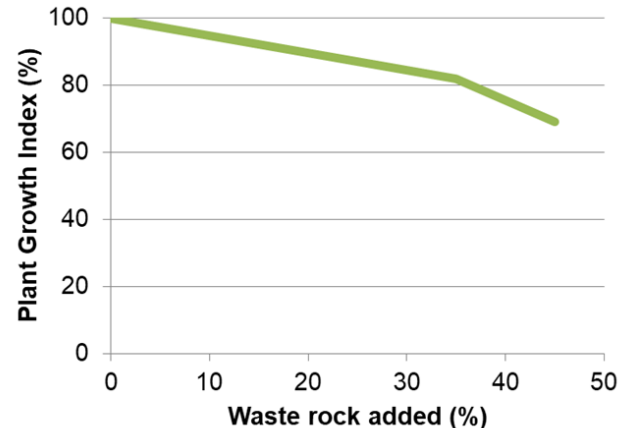

- Extractive waste was sieved to obtain the **fine fraction** (< 2 mm, sieve size). Fine fraction was analyzed for its use as **additive to soil**.
- Experiments were conducted on *Lepidium sativum* seeds.

Germination test

Plant growth test

Dressing activities for coarse fraction

Metal recovery (in %)

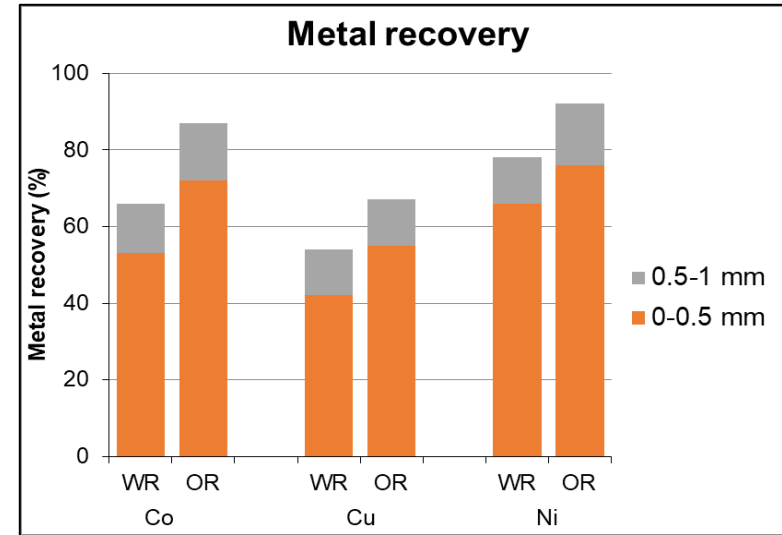

$$\frac{\text{Concentrate } x \cdot \text{Concentrate weight}}{\text{Feed } x \cdot \text{Feed weight}} \cdot 100$$

Shaking table:

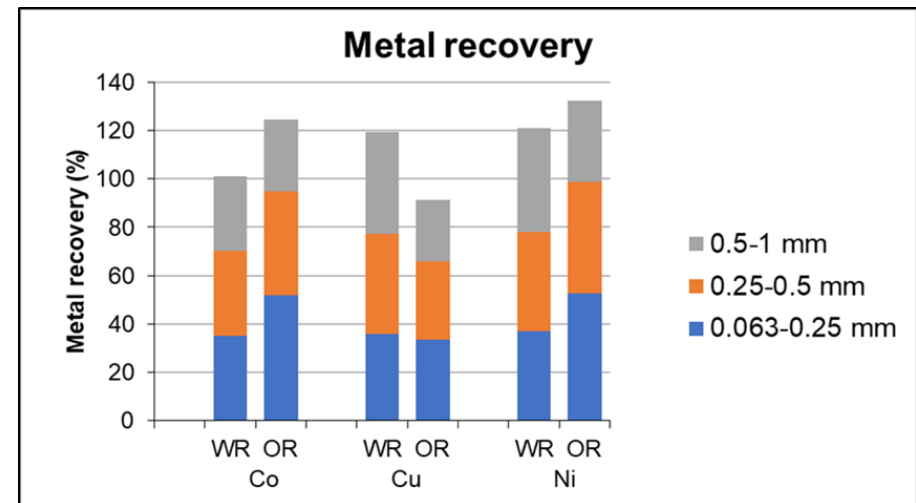

- Recovery of Co, Cu and Ni was higher for size fractions (0-0.5 mm) than 0.5-1 mm
- Recovery of Ni reached upto 76% for operating residues

Magnetic separation:

- Highest recovery reached upto 52% for nickel
- In general, showed lesser recovery than shaking table

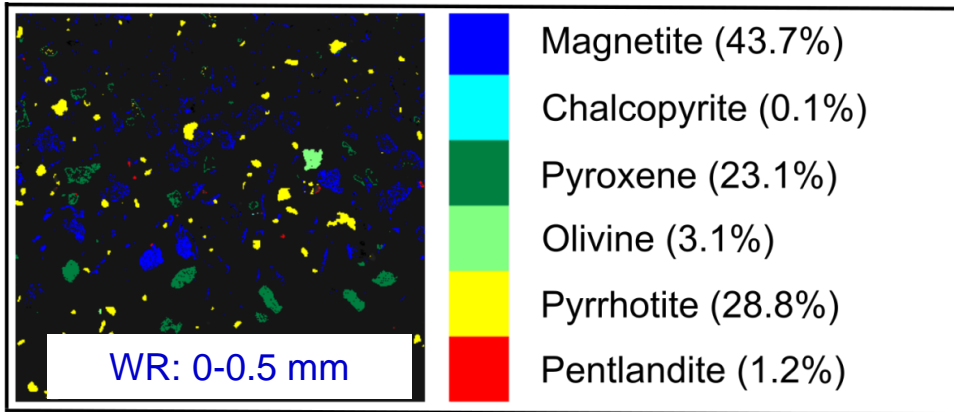

Shaking table

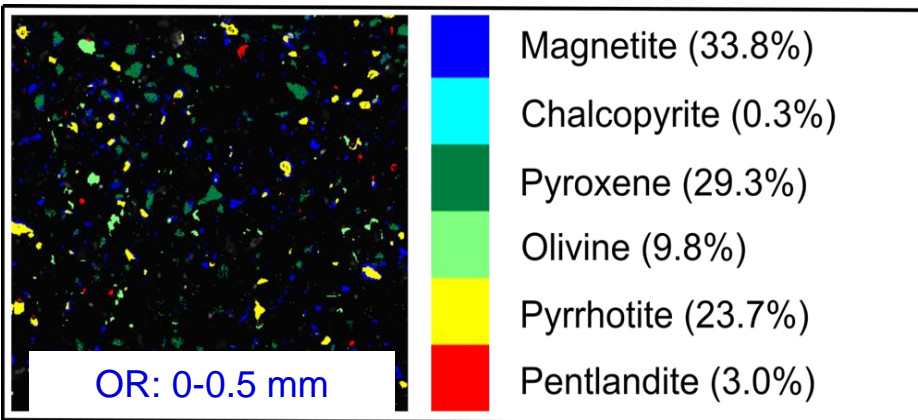

Magnetic separation

Mineral analysis (micro-XRF) after shaking table

Heavy fraction obtained from waste rock

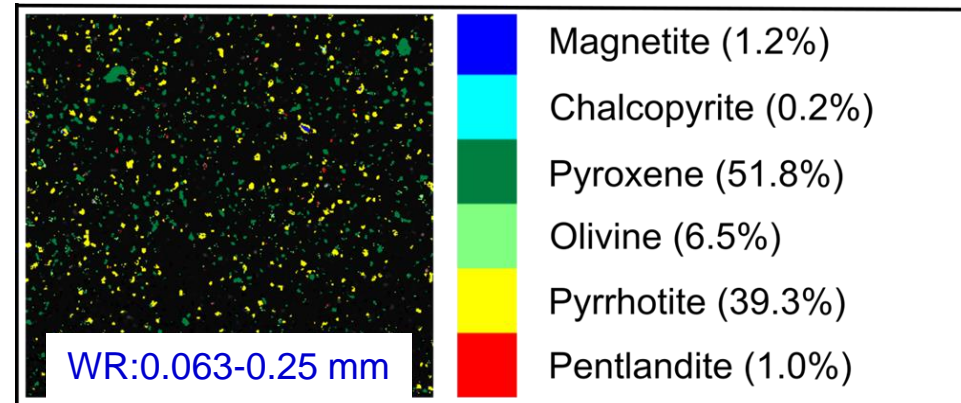

Heavy fraction obtained from operating residues

Mineral analysis after magnetic separation

Mineral maps of the magnetic fraction obtained after dressing activity:

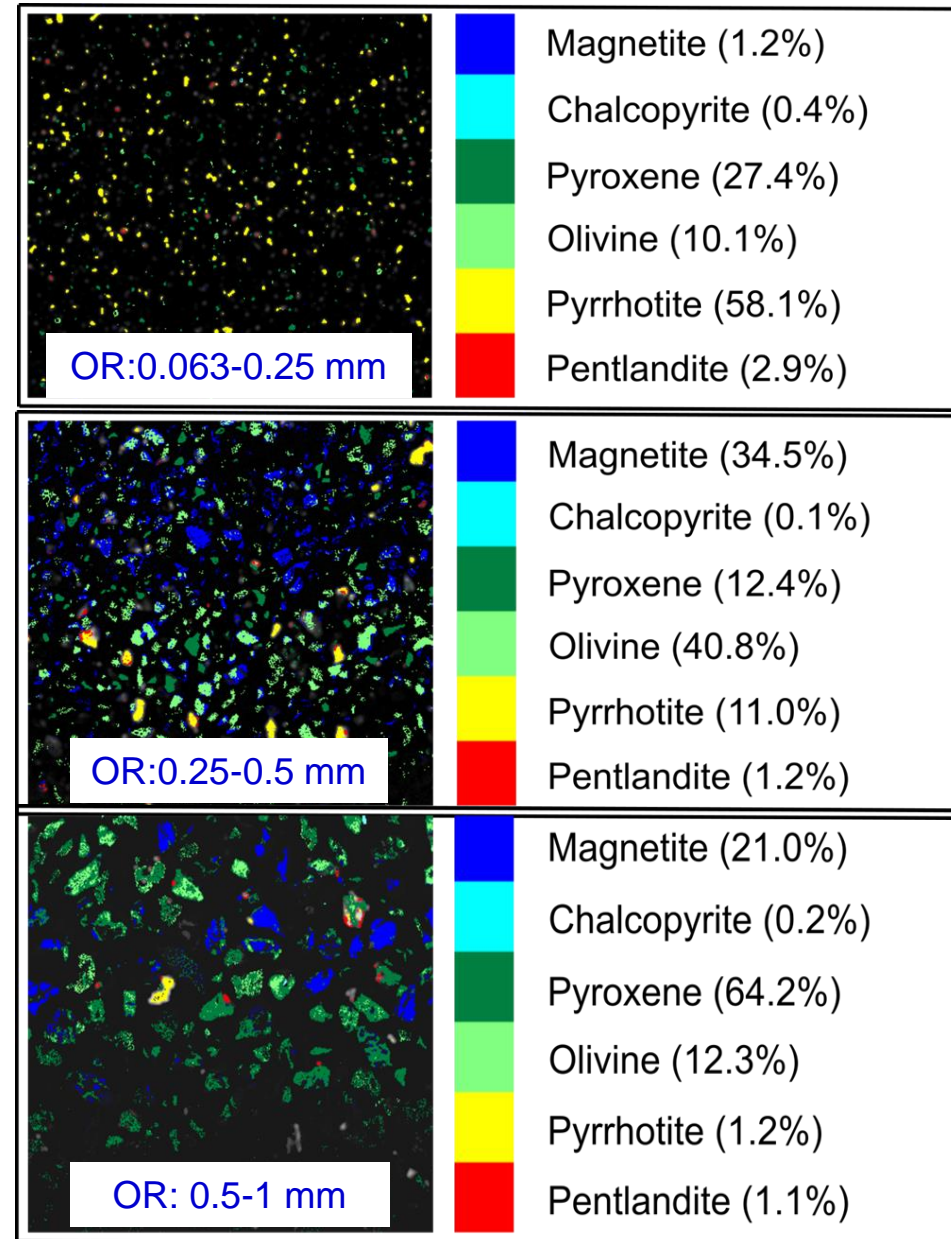

- The waste rock (0.063-0.25 mm) and (0.5-1 mm) indicate presence of pentlandite as c. 1%.
- The waste rock (0.25-0.5 mm) recorded highest presence of pentlandite as 1.4%.

Mineral analysis after magnetic separation

Mineral maps of the magnetic fraction obtained from operating residues:

- The OR (0.063-0.25 mm) recorded presence of pentlandite as 3%.
- The results indicated that both magnetic fraction and shaking table treatment almost led to same pentlandite% in the concentrate fractions.

Conclusions

- Fine fraction from waste rocks had major impacts on plant growth but not on seed germination. Thus with further amendment it is possible to use fine fraction for soil additive purposes.
- Pentlandite was 1% and Chalcopyrite as 3% in the **concentrate fractions** from the dressing activities.
- Changes in the geo-political and economic scenario are pushing nations towards procuring long lasting **raw material sources**.
- The present interdisciplinary research shows that extractive waste at abandoned mine sites can be use as raw material source in order to and generate **economic benefits and** reduce **environmental impacts**.
