Late Neogene carbonate productivity and terrigenous input in the central Western Pacific Warm Pool (IODP Site U1488)

Preliminary results … the stratigraphy

Anna Joy Drury, Thomas Westerhold, Ana Christina Ravelo, Ivano Aiello, Roy Wilkens, Ursula Röhl, Denise Kulhanek
International Ocean Discovery Program (IODP) Site U1488: Capturing climate evolution in the central Western Pacific Warm Pool

Figure 1. Map showing location of IODP Expedition 363 sites, and previously drilled DSDP/ODP sites. New data were generated at IODP Site U1488, which is located in the centre of the Western Pacific Warm Pool.

IODP Site U1488 captures late Miocene to present climate evolution

Figure 2. IODP Site U1488 spans ~0-10 Ma, with high enough sedimentation rates to capture orbital-scale climate dynamics. The high carbonate content and good foraminiferal preservation makes it a great site for geochemical studies.

Enabling continuous reconstruction of late Miocene-Present climate evolution: verifying and revising the shipboard composite depth scale and splice

Figure 3. The revised composite splice is shown here, with the composite core photos and shipboard GRA bulk density data.

- The shipboard composite depth scale and splice were revised using XRF core scanning data.
- Revisions were necessary because the high %CaCO_3 of the sediment meant physical property data were low amplitude.
- At Site U1488, these revisions ensure a ~330 m continuous composite section ...

... and will facilitate future high-resolution and continuous palaeoceanographical studies.
