A. Overview

Main aim

Characterise and map landslide processes in data-poor regions, using locally detailed environmental information in a **landslide domains** framework.

Renee.Heijenk@kcl.ac.uk

B. Landslide domains background [1/2]

"Areas of similar physiographic, meteorological, climatic and geological characteristics that shaped the style of landsliding."

Dashwood et al. (2017)

- Mapping environmental characteristics that drive landslide processes,
- Use detailed landslide process information about a small part of the region to fill to fill in data-poor parts with similar environmental characteristics,

The Landslide Domains Map of Great Britain. Figure from BGS (2018).

C. Study area [1/2]

District of East Sikkim in India:

- Lesser and High Himalaya,
- On the Main Central Thrust zone which acts as a boundary between weak phyllites and mica schists, and hard gneiss.

Renee.Heijenk@kcl.ac.uk

C. Study area [2/2]

In many data-poor areas:

- systemic information on landslide occurrence is rarely available, other than near roads and towns;
- data about environmental characteristics is sparse.

We have supplemented the Geological Survey of India inventory (see section **D**. Landslide mapping).

Elevation model of East Sikkim, low (green) to high (brown), with capital (red), roads (black) and GSI landslide inventory (black dots).

Renee.Heijenk@kcl.ac.uk

D. Landslide mapping [1/3]

Using open-source Google Earth 3D we mapped in whole of southern Sikkim, India:

- Similar geology West and East,
- Results in similar landslide processes,
- Increased data.

D. Landslide mapping [2/3]

- 167 landslide mapped in East Sikkim, India,
- 389 features mapped in **southern Sikkim**:
 - 256 translational landslides,
 - 133 debris flows.
- Ground-truth through fieldwork February 2019

Renee.Heijenk@kcl.ac.uk

D. Landslide mapping [3/3]

- Main landslide types and processes that occur in Sikkim, India
 - Translational slides, with sub-types:
 - Rotational rock slide
 - Translational rock slide
 - Debris slide
 - Debris slide into debris flow
 - Debris flows
 - Rock falls
- Where material type could not be determined, the main type was used.

Renee.Heijenk@kcl.ac.uk

E. Landslide domains [1/5]

4 landslide domains mapped:

- Translational landslides mostly found on colluvial slopes
- Rock falls on upper parts of slope, debris slides on lower parts of slope
- 3. Debris flows
- 4. Rock falls and slides driven by frost-thaw processes

Dominant variables for each process discussed in next slides.

Renee.Heijenk@kcl.ac.uk

E. Landslide domains [2/5]

Landslide domain 1

- Relatively soft phyllites,
- Colluvial slopes with creep observed and more active debris slides,
- Based on and delineated by lithology.

Renee.Heijenk@kcl.ac.uk

E. Landslide domains [3/5]

Landslide domain 2

- Relatively hard quartzites,
- Rock falls and slides observed at the top of slopes,
- Predominantly wedge failures
- Based on field observations, delineated by lithology.

F. Summary

- Using additional data from similar geology East Sikkim (900 km²) can be characterised into four landslide domains using limited data.
- These four landslide domains define regions of common processes.
- Landslide domains in general are an efficient method to categorise landslide processes, leading to better understanding of landslide susceptibility.
