Modeling of the Pohang Earthquake Probability Using the Seismogenic Index

Serge A. Shapiro (Freie Universität Berlin)

Kwang-Hee Kim (Pusan National University)

Jin-Han Ree (Seoul National University)

The Gutenberg-Richter law of injection-induced seismicity

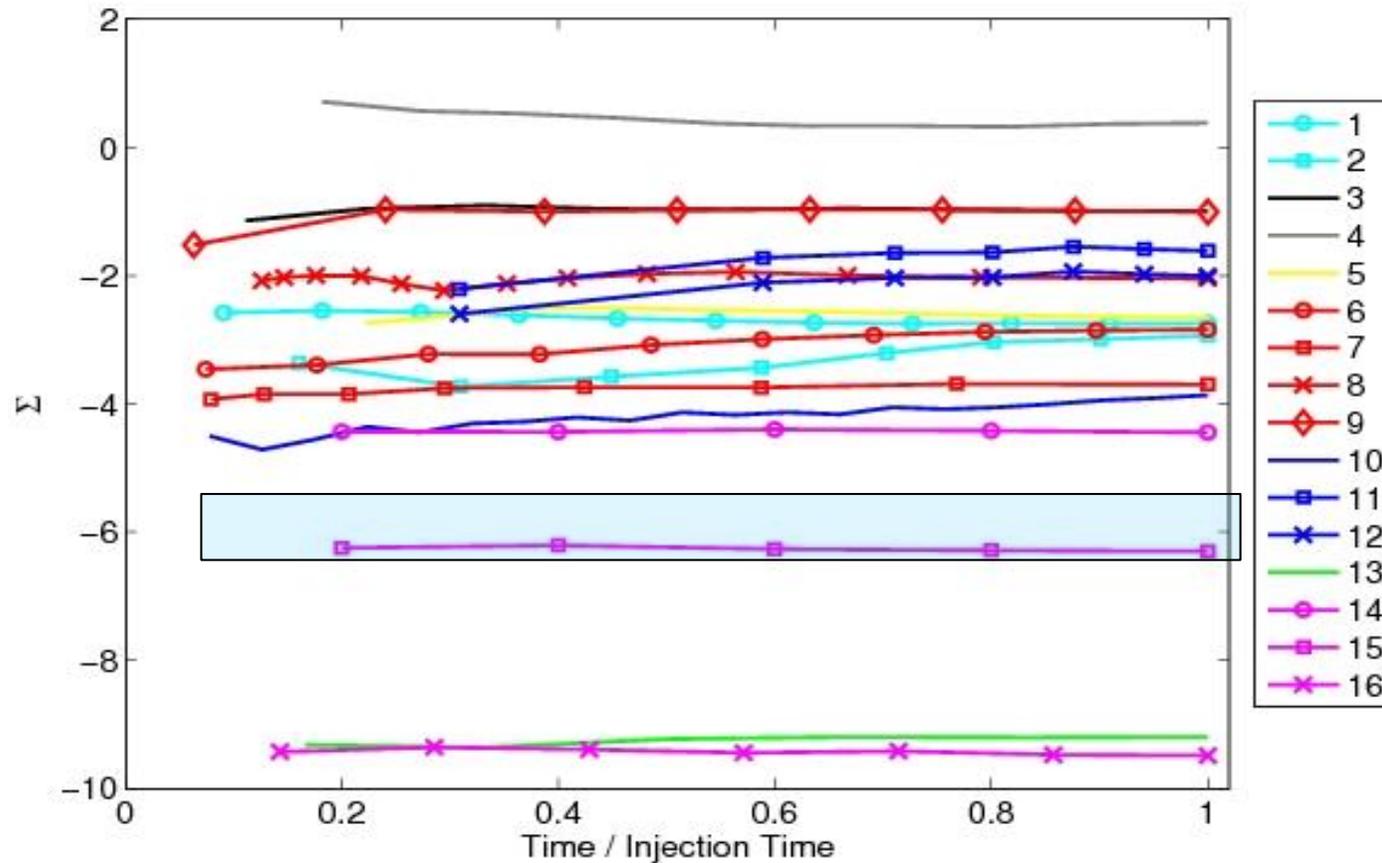

$$\log N_M(t) = a(t) - bM$$

$$\log N_M(t) = \Sigma + \log Q_{inject}(t) - bM$$

Seismogenic Index: Σ

Korean Government Commission Report, 2019

Fig. A-4-2. Temporal distribution of EGS project activity and seismicity of events whose magnitude was determined.

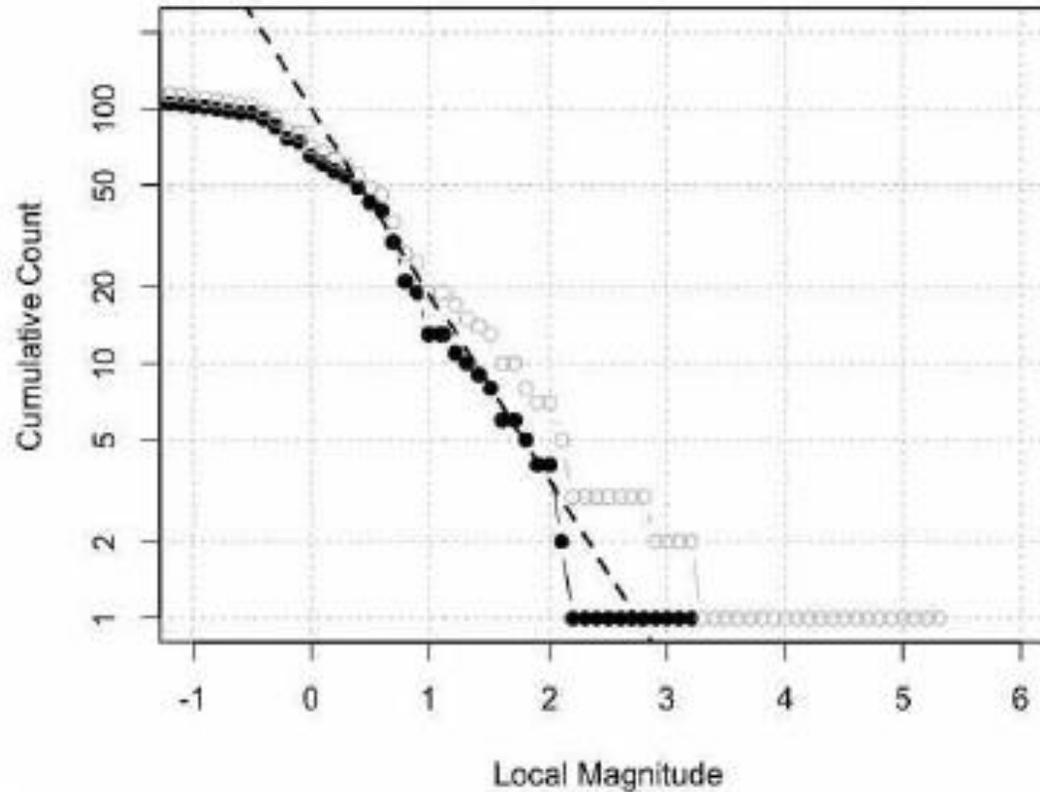

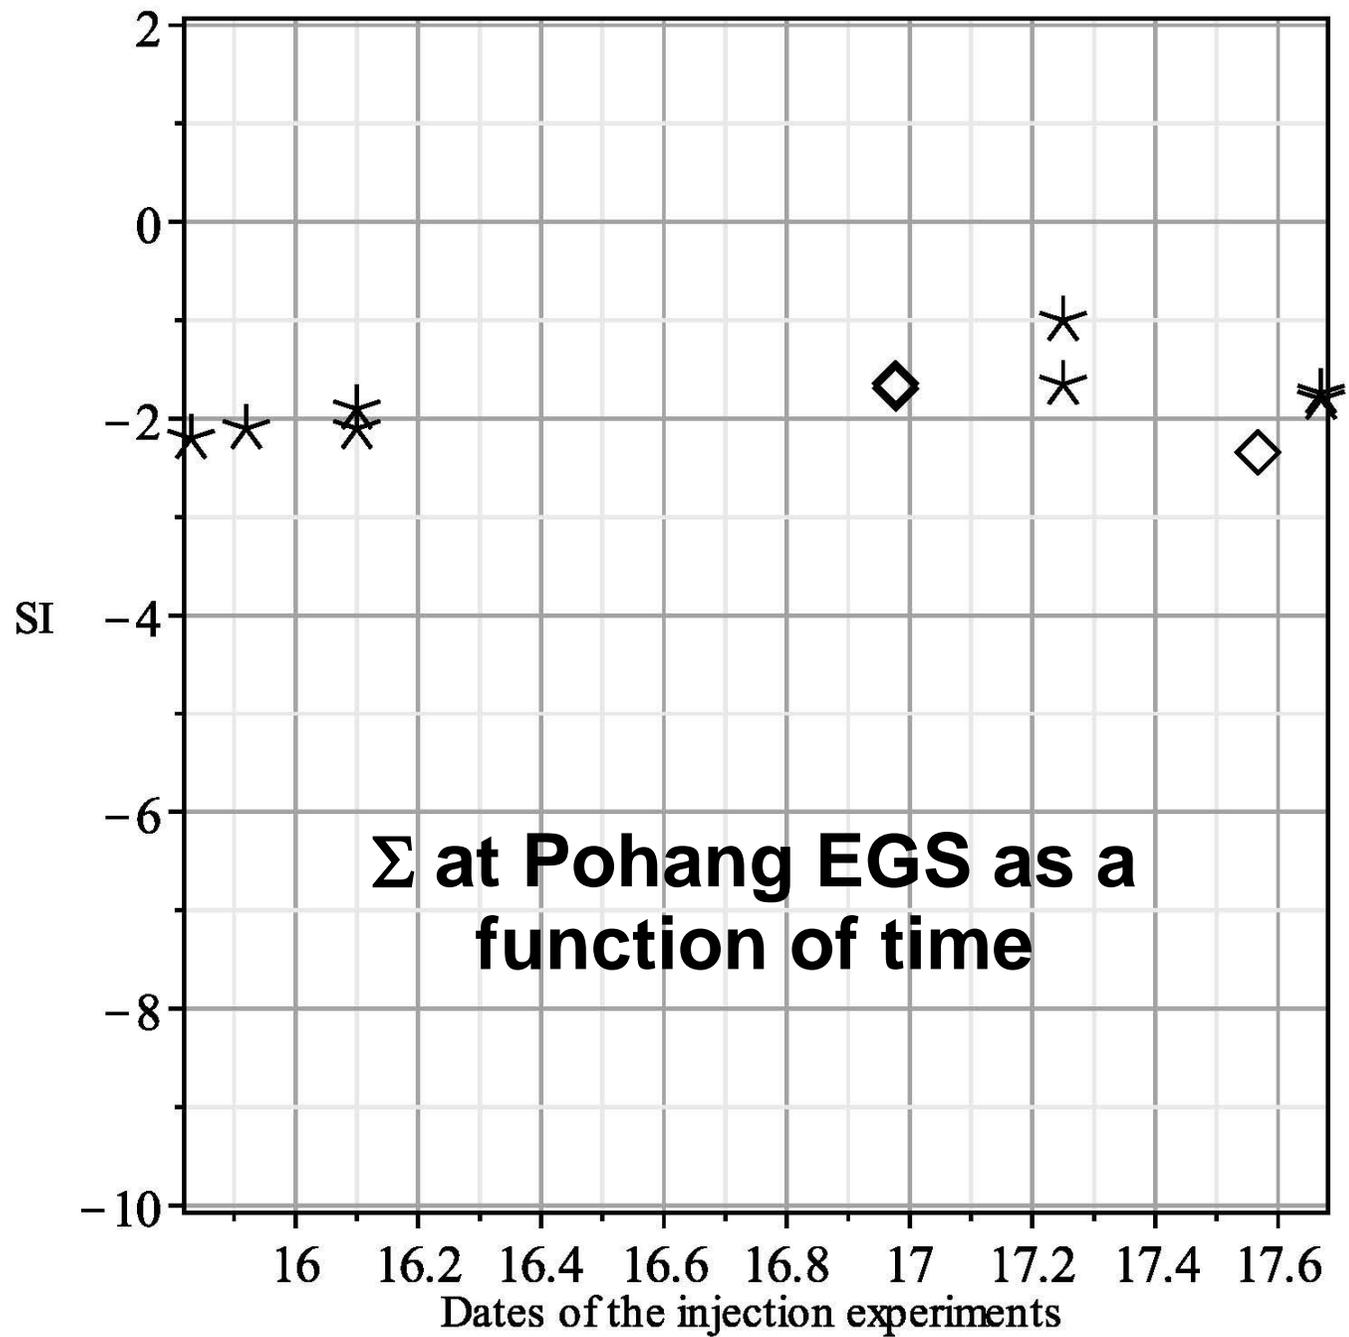

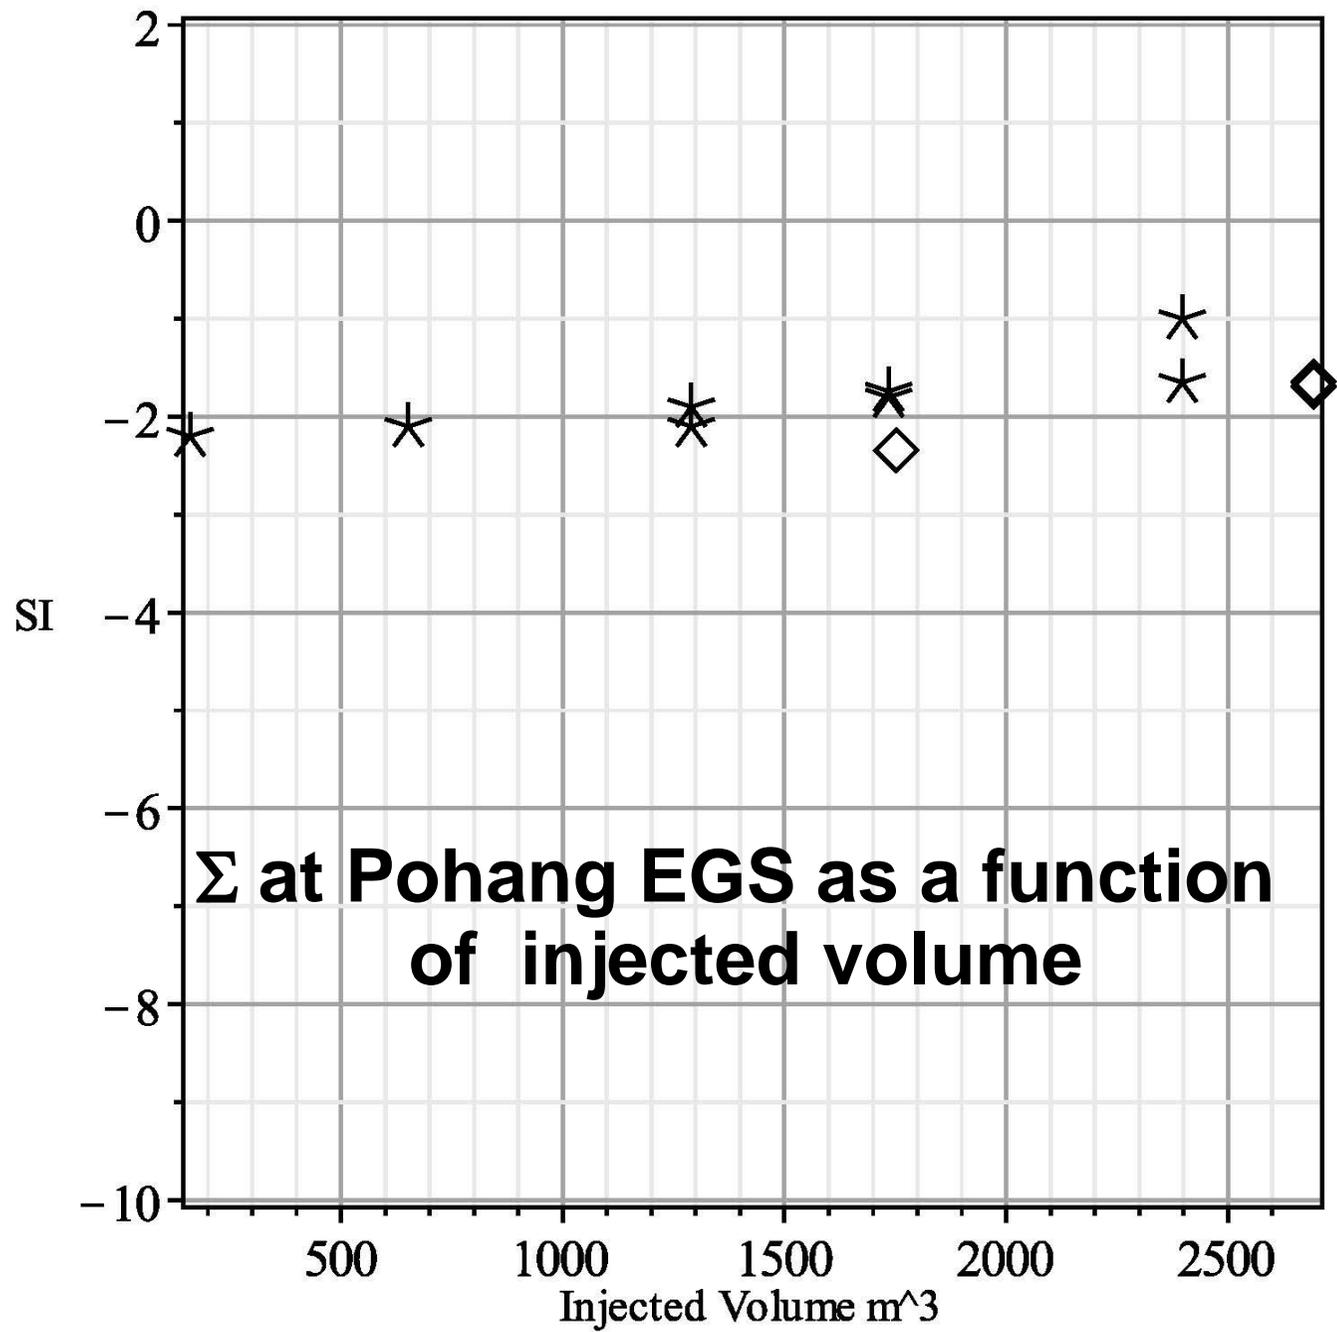

Figure O-12. Gutenberg-Richter magnitude frequency diagram. Solid symbols correspond to earthquakes occurring during or following the five well stimulations at the Pohang EGS facility. The dashed line has the formula $\log_{10}(N) = 2.0 - 0.73 M_L$ and was determined using the method of *Tinti and Mulargia* [1985]. Open symbols include foreshocks, mainshock and stimulation events.

Simplifying Assumptions

- An effective homogeneous infinite porous continuum.
- Monotonic independent injections.
- A complete recharge during the time periods between injections.
- Triggering by pore pressure.

Poisson Process: Event Probability

$$W_{ev \geq M} = 1 - \exp[-N_M]$$

$$W_{ev \geq Mmax} = 1 - \exp[-1] \approx 0.63$$

$$W_{ev \geq M} = 1 - \exp[-V_f(t)10^{\Sigma - bM}]$$

Conclusions

The seismogenic index, Σ , of the Pohang site is approximately between -2 and -1 . During the stimulation, we observe a tendency of Σ to increase with time: possibly an indication of a gradual stimulation of seismically more active zones.

The event of Mw3.3 on April 15th of 2017 indicated a jump of Σ to -1 .

Our estimate of the probability of the Pohang earthquake is approximately 15%.

One of decisive factors was the low b value. A combination of a low b-value and a rather high seismogenic index made the probability of the Mw5.5 event significant.

A termination of all injection operations after the Mw3.3 event would reduce the probability of an Mw5.5 event down to approximately 3%. Their termination at Mw2.3 would reduce it down to approximately 1%.

A real-time seismic monitoring permitting a precise 3-D event location and an estimating of the temporal evolutions of the stimulated volume geometry and of the seismogenic index could potentially help to prevent or to delay the occurrence of such an earthquake.
