Data

All ASTER, ArcticDEM and REMA DEMs intersecting glaciers worldwide:

- Stereo and bias-corrections (*Girod et al., 2017*): 5 million CPU hours
- DEM coverage equivalent to 20 times the land area on Earth

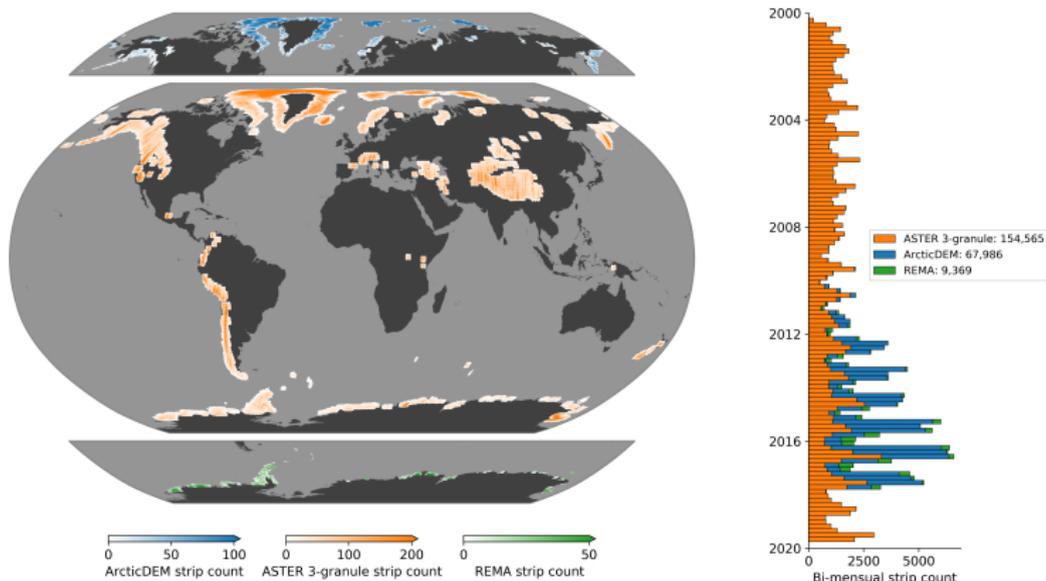

Figure: ASTER, ArcticDEM REMA data coverage

Methods

Continuous glacier surface elevation time series based on Gaussian Process approaches: *(Rasmussen and Williams, 2006)*

- Prior covariances estimated empirically in order to: **remove outliers (filtering)**, then **mitigate effects of seasonality while conserving nonlinear changes (fitting)**

- Half a billion pixels resolved independently at a resolution of 100 m: **99,9% of Earth's glaciers, over 97,4% of their surface with 39 observations in time per pixel on average**

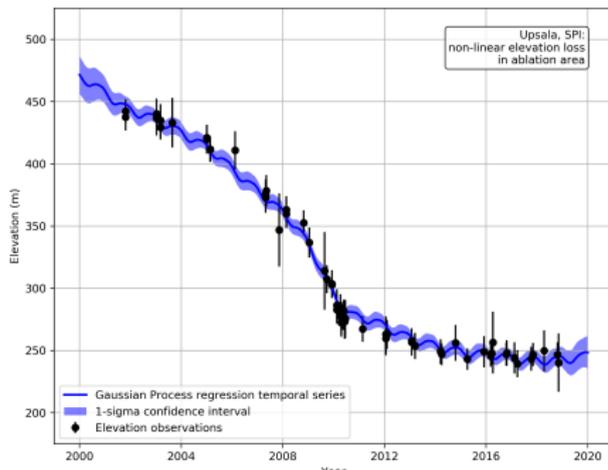

Figure: A pixel on the tongue of Upsala, SPI, Argentina

Validation and uncertainty analysis

All ICESat and IceBridge campaigns on glaciers:

- 25 million high-precision measurements spanning 2003-2019 **intersected at the same points in space and time than our time series**
- Reveal the **absence of elevation change bias in our time series** ($<0.01 \text{ m yr}^{-1}$ globally), conservative uncertainties and method robustness to multiple variables (low-texture areas, time lag to closest observation)
- Allow the study of the **spatiotemporal correlations structural to our interpolated elevation time series** for rigorous uncertainty propagation when integrating into volume and mass change time series

Region focus: Iceland

Region focus: High Mountain Asia

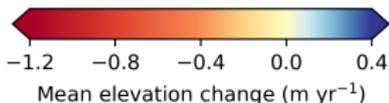

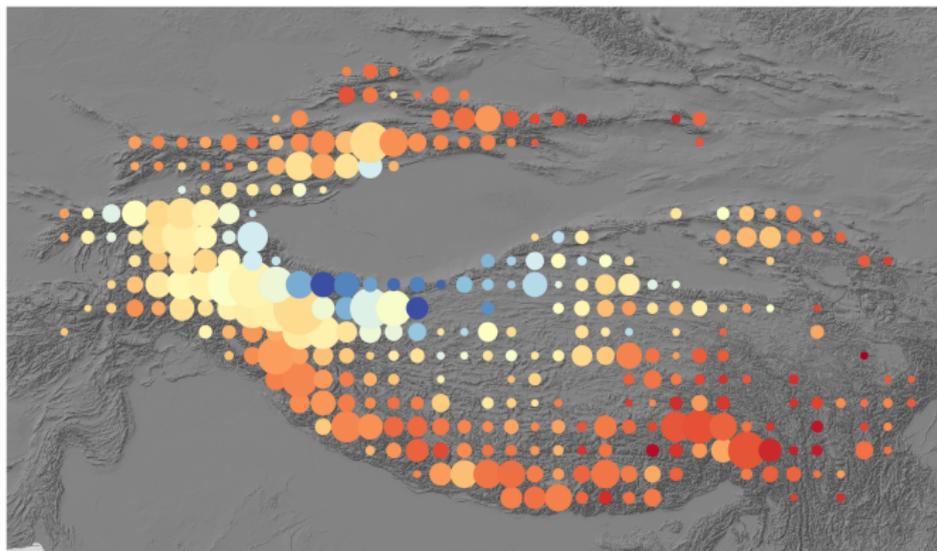

Generalized acceleration of thinning: the end of the Karakorum anomaly?

2000-2004, 2005-2009, 2010-2014, **2015-2019**

Region focus: High Mountain Asia

HMA mass change estimate:

- Thinning rates triple between 2000-2004 (-0.11 ± 0.05 m w.e. yr^{-1}) and 2015-2019 (-0.32 ± 0.05 m w.e. yr^{-1})
- Over 2000-2018, our estimate yields -0.21 ± 0.02 m w.e. yr^{-1} in good agreement with -0.19 ± 0.03 m w.e. yr^{-1} (Shean et al., 2020). The fact that our estimate is more negative may arise from the acceleration isolated by our time series that cannot be captured by linear-based approaches.

Conclusions

Our study presents:

- **A comprehensive surface elevation observational coverage** of 99.9% of inventoried glaciers over 20 years, rendered possible by the massive exploitation and correction of underexploited optical archives
- **A time-continuous approach to study Earth's surface elevation** based on statistical modelling methods, validated massively to independent high-precision datasets
- **A spatiotemporal methodology to improve uncertainty propagation to glacier volume and mass change** by accounting for spatial and temporal correlations in glacier elevation estimates

These advances combined make possible this **globally complete, spatiotemporally resolved estimate of glacier mass change for 2000-2019**. Data and further results will be made available at publication. In the meantime, don't hesitate to contact us if you need a snapshot of your favorite glacier :D !
