Introduction

Plastification by high pressure torsion

Experiments on joint compression and torsion of samples show the existence of two mechanisms of plastic deformation. The first of them is associated with the formation of Chernov–Luders bands at the macro level, and the second one is realized at the mesoscale due to the rotation of grains (blocks) of a structurally inhomogeneous material. In this presentation we simulate this process based on the equations of a multi-blocky medium with compliant interlayers and on the basis of Cosserat equations.

Elastic blocks and elastic interlayers

A motion of each block is defined by the system of equations of a homogeneous isotropic elastic medium:

\[
\begin{align*}
\rho \ddot{v}_1 &= \sigma_{11,1} + \sigma_{12,2} \\
\rho \ddot{v}_2 &= \sigma_{12,1} + \sigma_{22,2} \\
\dot{\sigma}_{11} &= \rho c_1^2 (v_{1,1} + v_{2,2}) - 2 \rho c_2^2 v_{2,2} \\
\dot{\sigma}_{22} &= \rho c_1^2 (v_{1,1} + v_{2,2}) - 2 \rho c_2^2 v_{1,1} \\
\dot{\sigma}_{12} &= \rho c_2^2 (v_{2,1} + v_{1,2})
\end{align*}
\]

Elastic interlayer between the horizontally located nearby blocks is described by the system of equations:

\[
\begin{align*}
\rho' \dot{v}_1^+ + \dot{v}_1^- &= \frac{\sigma_{11}^+ - \sigma_{11}^-}{\delta_1}, \quad \dot{\sigma}_{11}^+ + \dot{\sigma}_{11}^- &= \rho' c_1' 2 \frac{v_1^+ - v_1^-}{\delta_1}; \\
\rho' \dot{v}_2^+ + \dot{v}_2^- &= \frac{\sigma_{12}^+ - \sigma_{12}^-}{\delta_1}, \quad \dot{\sigma}_{12}^+ + \dot{\sigma}_{12}^- &= \rho' c_2' 2 \frac{v_2^+ - v_2^-}{\delta_1}
\end{align*}
\]

Elastic interlayer between the vertically located nearby blocks is modeled using similar system:

\[
\begin{align*}
\rho' \dot{v}_2^+ + \dot{v}_2^- &= \frac{\sigma_{22}^+ - \sigma_{22}^-}{\delta_2}, \quad \dot{\sigma}_{22}^+ + \dot{\sigma}_{22}^- &= \rho' c_1' 2 \frac{v_2^+ - v_2^-}{\delta_2}; \\
\rho' \dot{v}_1^+ + \dot{v}_1^- &= \frac{\sigma_{12}^+ - \sigma_{12}^-}{\delta_2}, \quad \dot{\sigma}_{12}^+ + \dot{\sigma}_{12}^- &= \rho' c_2' 2 \frac{v_1^+ - v_1^-}{\delta_2}
\end{align*}
\]
To take into account the plasticity, constitutive equations of the vertical elastic interlayer are replaced by the variational inequality:

\[
(\delta\sigma_{11}^+ + \delta\sigma_{11}^-) \dot{\varepsilon}_{11}^p + (\delta\sigma_{12}^+ + \delta\sigma_{12}^-) \dot{\varepsilon}_{12}^p \leq 0
\]

\[
\delta\sigma_{jk}^\pm = \tilde{\sigma}_{jk}^\pm - \sigma_{jk}^\pm \quad \text{variations of stresses}
\]

\[
\dot{\varepsilon}_{11}^p = \frac{v_1^+ - v_1^-}{\delta_1} - \frac{\dot{\sigma}_{11}^+ + \dot{\sigma}_{11}^-}{2\rho'c_1'2}, \quad \dot{\varepsilon}_{12}^p = \frac{v_2^+ - v_2^-}{\delta_1} - \frac{\dot{\sigma}_{12}^+ + \dot{\sigma}_{12}^-}{2\rho'c_2'2} \quad \text{plastic strain rates}
\]

The actual stresses \(\sigma_{jk}^\pm\) and variable stresses \(\tilde{\sigma}_{jk}^\pm\) are subjected to the constraint in the form:

\[
f\left(\frac{\tilde{\sigma}_{11}^+ + \tilde{\sigma}_{11}^-}{2}, \frac{\tilde{\sigma}_{12}^+ + \tilde{\sigma}_{12}^-}{2}\right) \leq \tau(\chi)
\]

\(\tau\) – material yield point of interlayers, \(\chi\) – a material parameter (or set of parameters) of hardening

\(f(\sigma_n, \sigma_\tau)\) – equivalent stress function, in which arguments are normal and tangential stresses

The simplest form of the constraint for a microfractured medium is as follows:

\[
|\sigma_\tau| \leq \tau_s - k_s \sigma_n \quad (\tau_s \text{ and } k_s \text{ – material parameters})
\]

Constitutive equations of the horizontal elastic-plastic interlayer are formulated in a similar way.
Poynting–Thomson’s viscoelastic model

To describe the viscous dissipative effects in the interlayers under shear stresses, the Poynting–Thomson model of a viscoelastic medium is used.

\[
\varepsilon'_{12} = a_0 \left( \sigma^+_{12} + \sigma^-_{12} \right)/2, \quad \varepsilon''_{12} = a_1 s_{12}
\]

Hooke’s law for elastic element:

\[
\eta \dot{\varepsilon}''_{12} = (\sigma^+_{12} + \sigma^-_{12})/2 - s_{12}
\]

Newton’s law for viscous element:

Total strain: \( \varepsilon_{12} = \varepsilon'_{12} + \varepsilon''_{12} \)

Constitutive equations of the interlayer:

\[
a_0 \frac{\sigma^+_{12} + \sigma^-_{12}}{2} + a_1 \dot{s}_{12} = \frac{v_2^+ - v_2^-}{\delta_1}, \quad \frac{\sigma^+_{12} + \sigma^-_{12}}{2} = s_{12} + \eta a_1 \dot{s}_{12}
\]

Energy balance equation:

\[
\frac{\sigma^+_{12} + \sigma^-_{12}}{2} \frac{v_2^+ - v_2^-}{\delta_1} = W + \eta a_1^2 s_{12}^2, \quad 2W = a_0 \left( \frac{\sigma^+_{12} + \sigma^-_{12}}{4} \right)^2 + a_1 s_{12}^2
\]

according to which the power of internal stresses in the interlayer is the sum of the reversible elastic strain power and the power of the viscous energy dissipation.
A blocky medium with weakened interlayers: Cracking of interlayers

Model of separation cracks

\[ \delta \sigma_{11} \left( \frac{1}{\rho' c_1^2} \sigma_{11} - \varepsilon_{11} \right) \geq 0, \quad \dot{\varepsilon}_{11} = \frac{v_1^+ - v_1^-}{\delta_1} \]

Conditions of contact interaction of the crack edges are formulated as a variational inequality:

The algorithm of numerical implementation in a mesh of a grid is based on the equations

\[ \hat{\varepsilon}_{11} = \varepsilon_{11} + \frac{v_1^+ - v_1^-}{\delta_1} \tau, \quad z_1 v_1^+ + \sigma_{11}^+ = R_1^+, \quad z_1 v_1^- - \sigma_{11}^- = R_1^- \]

and the closing equation \( \dot{\sigma}_{11} + \sigma_{11} = \sigma_{11}^+ + \sigma_{11}^- \), guaranteeing the absence of artificial dissipation of energy, which gives the procedure of stress correction:

\[ \dot{\sigma}_{11} = \frac{1}{\kappa} \pi_+ \left( \varepsilon_{11} + \frac{R_1^+ - R_1^- - \sigma_{11}}{z_1 \delta_1} \tau \right), \quad \kappa = \frac{1}{\rho' c_1^2} + \frac{\tau}{\rho c_1 \delta_1} \]
Model of porous interlayers

The longitudinal deformation of the interlayers is described on the basis of a complicated version of the porous elastic model, which takes into account the nonlinear threshold behavior of a material with the strength increasing during the collapse of pores.

Total strain: \[ \varepsilon_{11} = \frac{\sigma'_{11}}{b_1} + \theta_1 - \theta_0 \]
\[ \sigma'_{11} \leq 0 \quad \text{stress in a rigid contact, } \theta_0 > 0 \quad \text{and} \quad \theta_1 \geq 0 \quad \text{– initial and current porosity values} \]

Governing relationships of a rigid contact:
\[ (\tilde{\sigma}_{11} - \sigma'_{11}) \theta_1 \leq 0, \quad \tilde{\sigma}_{11}, \sigma'_{11} \leq 0 \]
\[ \sigma'_{11} = b_1 \pi(\theta_0 + \varepsilon_{11}), \quad \pi(\theta) = \min(\theta, 0) \quad \text{– projection onto the non-positive semi-axis} \]

Constitutive equations of the interlayer including the equation for porosity:
\[ \dot{\varepsilon}_{11} = \frac{v^+ - v^-}{\delta_1}, \quad \frac{\sigma_{11}^+ + \sigma_{11}^-}{2} = b_0 \varepsilon_{11} + b_1 \pi(\theta_0 + \varepsilon_{11}), \quad \theta_1 = \theta_0 + \varepsilon_{11} - \pi(\theta_0 + \varepsilon_{11}) \]

The energy balance equation:
\[ \frac{\sigma_{11}^+ + \sigma_{11}^-}{2} \dot{\varepsilon}_{11} = \dot{W}, \quad 2W = b_0 \varepsilon_{11}^2 + b_1 \pi^2(\theta_0 + \varepsilon_{11}) \]
Parallel computational algorithms

Two-cyclic splitting

We developed parallel computational algorithm for supercomputers of the cluster architecture based on a two-cyclic method of splitting, which has high accuracy and permits the efficient parallelization of computations.

Governing equations in blocks and interlayers are represented in the form of symbolic evolution equation:

\[ \dot{U} = A_1(U) + A_2(U) \]

\( A_1 \) and \( A_2 \) – nonlinear differential-difference operators, simulating 1D motion of a blocky medium in the direction of the coordinate axes \( x_1 \) and \( x_2 \)

\( U \) – vector–function of unknown quantities, which includes the projection of the velocity vector and the stress tensor in blocks and interlayers

The method of splitting on the time interval \((t_0, t_0 + \Delta t)\) includes 4 steps:

1) the step of solving 1D equation in the \( x_1 \) direction on the interval \((t_0, t_0 + \Delta t/2)\)
2) a similar step of solving the equation in the \( x_2 \) direction
3) the step of recomputation in the \( x_2 \) direction on the interval \((t_0 + \Delta t/2, t_0 + \Delta t)\)
4) the step of recomputation in the \( x_1 \) direction on the same time interval

\[ \dot{U}^{(1)} = A_1(U^{(1)}), \quad U^{(1)}(t_0) = U(t_0) \]
\[ \dot{U}^{(2)} = A_2(U^{(2)}), \quad U^{(2)}(t_0) = U^{(1)}(t_0 + \Delta t/2) \]
\[ \dot{U}^{(3)} = A_2(U^{(3)}), \quad U^{(3)}(t_0 + \Delta t/2) = U^{(2)}(t_0 + \Delta t/2) \]
\[ \dot{U}^{(4)} = A_1(U^{(4)}), \quad U^{(4)}(t_0 + \Delta t/2) = U^{(3)}(t_0 + \Delta t) \]

The solution at the time instant \( t_0 + \Delta t \) equals to \( U(t_0 + \Delta t) = U^{(4)}(t_0 + \Delta t) \)
Efficiency of parallelization

Computational algorithm is implemented as the parallel program for analysis of the waves propagation processes in blocky media under external dynamic loads. The parallelization is performed on the basis of domain decomposition – each processor of a cluster expects a separate chain of blocks including the boundary interlayers in the horizontal direction. The programming language is Fortran, and the message passing interface (MPI) library is used.

Dependence of the runtime $T$ on the linear dimension $N$ of a grid in blocks (circle points – actual computational time, solid line – semi-theoretical computational time)
Results of computations

Orthotropic elastic Cosserat continuum

For plane strain, the equations of the Cosserat elastic continuum:

\[
\begin{align*}
\rho_0 \dot{v}_1 &= \sigma_{11,1} + \sigma_{12,2}, & \rho_0 \dot{v}_2 &= \sigma_{21,1} + \sigma_{22,2} \\
J_0 \dot{\omega}_3 &= \mu_{31,1} + \mu_{32,2} + \sigma_{21} - \sigma_{12} \\
a_1 \dot{\sigma}_{11} - b_1 \dot{\sigma}_{22} &= v_{1,1}, & a_1 \dot{\sigma}_{22} - b_1 \dot{\sigma}_{11} &= v_{2,2} \\
a_2 \dot{\sigma}_{21} - b_2 \dot{\sigma}_{12} &= v_{2,1} - \omega_3 \\
a_2 \dot{\sigma}_{12} - b_2 \dot{\sigma}_{21} &= v_{1,2} + \omega_3 \\
\dot{\mu}_{31} &= \alpha_2 \omega_{3,1}, & \dot{\mu}_{32} &= \alpha_2 \omega_{3,2}
\end{align*}
\]

written in Cartesian coordinates relative to the linear velocities \(v_1, v_2\), angular velocity \(\omega_3\), stresses \(\sigma_{jk}\) and couple stresses \(\mu_{jk}\) can be represented in the matrix form:

\[
A \frac{\partial U}{\partial t} = B^1 \frac{\partial U}{\partial x_1} + B^2 \frac{\partial U}{\partial x_2} + Q U, \quad U = (v_1, v_2, \omega_3, \sigma_{11}, \sigma_{22}, \sigma_{21}, \sigma_{12}, \mu_{31}, \mu_{32})
\]

with symmetric matrix-coefficients \(A, B^1, B^2\) and antisymmetric matrix \(Q\).

This system belongs to the class of symmetric \(t\)-hyperbolic systems by Friedrichs and systems of thermodynamically consistent conservation laws by Godunov.
Elastic-plastic Cosserat continuum

It is possible to construct a model of elastic-plastic Cosserat continuum on the basis of the system of equations of the theory of elasticity. Such a model is formulated as a variational inequality:

$$(\tilde{U} - U) \cdot \left( A \frac{\partial U}{\partial t} - B^1 \frac{\partial U}{\partial x_1} - B^2 \frac{\partial U}{\partial x_2} - QU \right) \geq 0, \quad \tilde{U}, U \in F$$

$F$ – set of admissible variations of vector $U$; $\tilde{U}$ – an arbitrary element of $F$

This variational inequality is a formulation of von Mises principle of maximum power of plastic dissipation. The boundary of $F$ in the space of stress and couple stress tensors is the yield surface of a material, which is equivalent to the system of constitutive equations of plasticity in the form of associative flow rule.

Plasticity in interlayers

Since the behavior of continuum is completely determined by the deformation properties of the weakened interlayers of blocky structure, the yield criterion is used in the form:

\[
\begin{align*}
|\sigma_{21}| & \leq \tau_0 - \kappa \tau \sigma_{11}, \\
|\sigma_{12}| & \leq \tau_0 - \kappa \tau \sigma_{22} \\
|\mu_{31}| & \leq \mu_0 - \kappa \mu \sigma_{11}, \\
|\mu_{32}| & \leq \mu_0 - \kappa \mu \sigma_{22}
\end{align*}
\]

It limits the tangential stresses, which characterize shifts along the interlayers, and couple stresses, the attainment of which limit values lead to an irreversible change in the curvature.

The yield strengths of the seams during shear $\tau_0$ and bending $\mu_0$ were taken equal to 0.86 MPa and 8.8 kPa·m, respectively. Material hardening due to compression was not taken into account. To analyze the influence on the process of deformation of various factors – shear and curvature deformations – one of the two yield strengths was assigned a value exceeding the stress level in the problem with elastic interlayers.

Squeezing of a medium by rotating plate

The solution under high shear plasticity, when $\tau_0 \to 0$ and $\mu_0$ is sufficiently high:

$$
\sigma_{21} = \sigma_{12} = 0, \quad \sigma_{11,1} = \sigma_{22,2} = 0
$$

$$
\mu_{31,1} + \mu_{32,2} = 0
$$

$$
\mu_{31} = \alpha_2 \varphi_{3,1}, \quad \mu_{32} = \alpha_2 \varphi_{3,2}
$$

Hence, $\sigma_{22} = -\gamma x_1$, $\sigma_{11} = 0$, and the angle of rotation $\varphi_3$ is a harmonic function

(it satisfies the Laplace equation):

$$
\varphi_3 = -x_2 \varepsilon_0 t_0^2/(2h)
$$

$$
u_1 = \frac{\gamma}{2} \left( b_1 x_1^2 + a_1 x_2^2 \right), \quad u_2 = -\gamma a_1 x_1 x_2, \quad \gamma = \frac{\varepsilon_0 t_0^2}{2 a_1 h}\n$$
Results of computations

In the case of high bending plasticity $\mu_0 \rightarrow 0$ and $\tau_0$ is sufficiently high. Then the equations of plane problem of static elasticity are fulfilled with $\varphi_3 = (u_{2,1} - u_{1,2})/2$.

Numerical solution of the problem with sufficiently low yield strengths repeats the qualitative features of these solutions.

Conclusions

To study wave processes in structurally inhomogeneous media, a discrete-continuous model of a blocky structure composed of elastic blocks is proposed, accounting irreversible deformation and fracture of weakened interlayers.

An alternative approach is developed based on the Cosserat model of the orthotropic continuum, taking into account the plastic deformation of a material. Comparative analysis showed that by appropriate choosing the mechanical parameters of the Cosserat continuum, it is possible to achieve agreement on the results both on a qualitative and quantitative levels.

The hypothesis, that the plasticization of a structurally inhomogeneous material in the whole volume at the meso-level is due to the rotations of particles is confirmed in the problem of slow squeezing of a blocky medium by a rotating plate.

The developed computational algorithms and software can be used to test the adequacy of the formulas for calculating the parameters of the Cosserat continuum of blocky-layered structures obtained as a result of homogenization procedures.

The reported study was funded by the Russian Foundation for Basic Research, Government of Krasnoyarsk Territory, Krasnoyarsk Regional Fund of Science to the research project No. 18-41-242001.
