

# Inconsistencies in the **estimation of land surface temperature** from longwave radiation measurements

Gitanjali Thakur, Stan Schymanski, Kaniska Mallick, Ivonne Trebs, Mauro Suils  
*Luxembourg Institute of Science and Technology*

# LAND SURFACE TEMPERATURE (LST):

- LST is defined as the 'ensemble directional radiometric surface temperature' (Norman and Becker, 1995)
- LST is an important state variable in land atmosphere process.
  - It controls the energy and water exchange between the Earth's surface and the atmosphere.
  - It is widely used to estimate evapo-transpiration and vegetation water stress through surface energy balance models.

- 1: Introduction
  - 1.1 Background
  - 1.2 Objective
  - 1.3 Study sites
- 2. Objective 1
  - 2.1 Results
  - 2.2 Validation
- 3. Objective 2
  - 3.1 Holmes approach
  - 3.2 Results
  - 3.3 Validation
- 4. Conclusions

# LST ESTIMATION:

- The longwave measured using airborne radiance or tower mounted radiometers such as Eddy co-variance tower, is used with emissivity (known/assumed) to estimate LST ( $T_s$ ).
- The longwave balance and Stephan-Boltzmann law leads to complete equation (leq), which is solved to estimate LST.

## Complete equation (leq)

$$L_{up} = \epsilon \sigma T_s^4 + (1 - \epsilon) L_{down}$$

## Simplified equation (seq)

$$L_{up} = \epsilon \sigma T_s^4$$

**Absence of  $L_{down}$  in last decades and  $\epsilon$  close to 1**

where,  $L_{up}$  is the up-welling longwave,  $L_{down}$  is the down-welling longwave,  $\sigma$  is the Stephan-Boltzmann constant and  $\epsilon$  is the surface emissivity.

- 1. Introduction
  - 1.1 Background
  - 1.2 Objective
  - 1.3 Study sites
- 2. Objective 1
  - 2.1 Results
  - 2.2 Validation
- 3. Objective 2
  - 3.1 Holmes approach
  - 3.2 Results
  - 3.3 Validation
- 4. Conclusions

# LST ESTIMATION: @ LARGE AND PLOT SCALE

## Large scale (remote sensing):

- Radiance measured on daily basis is used to estimate LST, such as MODIS (Moderate Resolution Imaging Spectroradiometer)
- Remotely sensed LST values are widely used at regional and global scale.

Fig. 1 (a): Airborne radiometers<sup>[1]</sup>

## Plot scale:

- At plot scale both  $l_{eq}$  and  $seq$  are used to estimate LST with measured longwave and known emissivity.
- Mostly simplified equation is used for LST estimation, arguing MODIS emissivity is close to 1.

Fig. 1 (b): EC Tower at Adelaide river<sup>[2]</sup>

1. Introduction
  - 1.1 Background
  - 1.2 Objective
  - 1.3 Study sites
2. Objective 1
  - 2.1 Results
  - 2.2 Validation
3. Objective 2
  - 3.1 Holmes approach
  - 3.2 Results
  - 3.3 Validation
4. Conclusions

1. Introduction

  - 2.2 Validation
3. Objective 2
  - 3.1 Holmes approach
  - 3.2 Results
  - 3.3 Validation
4. Conclusions

Research Question 1.

**How the use of complete (*leq*) and simplified (*seq*) equation interchangeably @ plot scale leads to bias in LST estimation?**

Research Question 2.

**How can we obtain emissivity @ plot scale for LST estimation?**

# STUDY SITES:

- Seven sites<sup>[3]</sup> having good record of Eddy-covariance data, with different land cover types are selected across Australia for the analysis.

Table 1: Study sites for the analysis

Site Name	Land Cover types
Adelaide River	Savanna dominated by Eucalyptus
Alice Spring	Mulga Canopy
Howard Spring	Woodland Savanna
Litchfield	Tropical Savanna
Sturt Plains	Grassland (Mitchell grass)
Ti Tree East	Grassy mulga woodland & Triodia savanna
Tumbarumba	Wet Sclerophyll forest

  - 2.2 Validation
- 3. Objective 2
  - 3.1 Holmes approach
  - 3.2 Results
  - 3.3 Validation
- 4. Conclusions

$T_{MODIS} > T_{seq} > T_{leq}$

MODIS emissivity results high bias

Table 2. LST bias &  $R^2$  values @ study sites

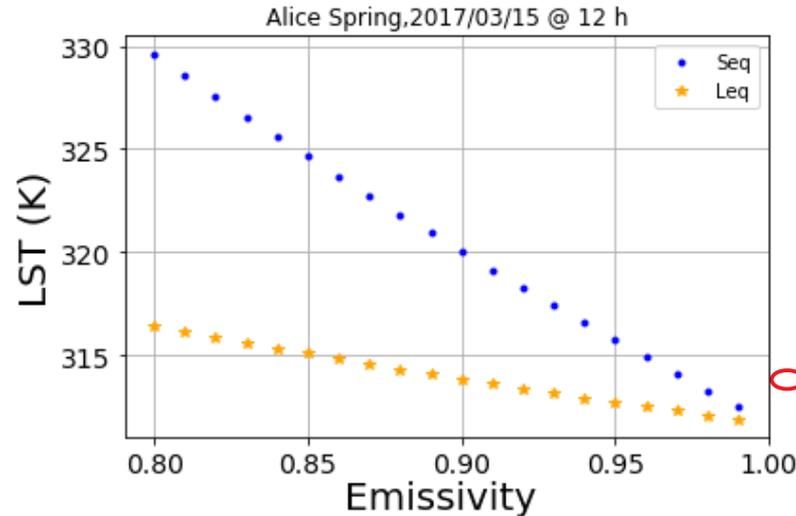

Site	seq		leq	
	$R^2$	Bias	$R^2$	Bias
Litchfield	0.40	10	0.41	11
Tumbarumba	0.89	0.99	0.89	1.93
Alice Springs	0.93	4.78	0.93	6.24
Howard Springs	0.16	8.99	0.16	9.90
Sturt Plains	0.80	3.67	0.81	4.61
Ti tree East	0.55	6.76	0.57	8.30
Adelaide River	0.19	2.61	0.27	3.47

Fig. 5: Plot showing LST bias @ Alice spring at MODIS measurement time

# LST SENSITIVITY TO EMISSIVITY:

$$T_{leq} = \sqrt[4]{\frac{L_{down}}{\sigma} - \frac{L_{down}}{\epsilon\sigma} + \frac{L_{up}}{\epsilon\sigma}}$$

$$T_{seq} = \sqrt[4]{\frac{L_{up}}{\epsilon\sigma}}$$

Seq is more sensitive to emissivity

Fig. 6: Plot showing sensitivity of estimated LST to emissivity range (0.8 to 1) using *seq* and *leq* @ Alice Spring

# OPTIMIZED EMISSIVITY & LST ESTIMATION:

## Theory

Sensible heat is driven by surface-air temperature difference

$$H = C \Delta T$$

$$H = 0 \text{ when } \Delta T = 0$$

Regression line of H vs  $\Delta T$   
goes through  
0 if LST estimates are correct

**Step 1:** Assume range of  $\epsilon$  values (0.99 to 0.4)

**Step 2:** Calculate LST ( $T_s$ ) for each value of emissivity

**Step 3:** Plot sensible heat (H) vs ( $T_s - T_a$ ), fit regression forced through origin and compute  $R^2$  and root mean square error (RMSE)

**Step 4:** Calculate RMSE,  $R^2$  values for each emissivity.

**Step 5:** If  $R^2 > 0.5$ , choose emissivity value resulting in lowest RMSE

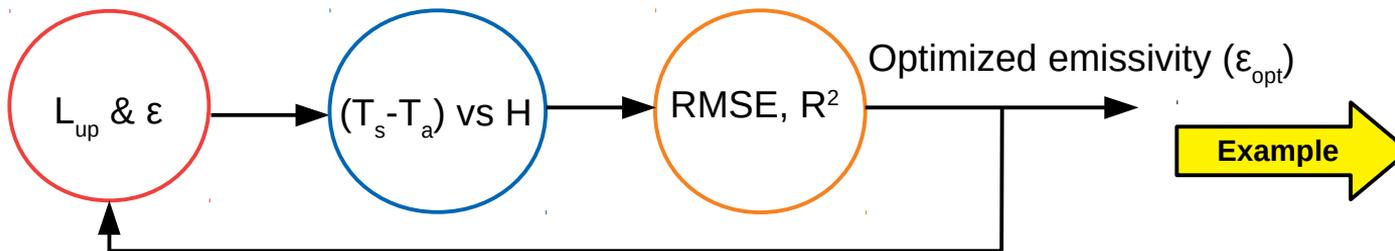

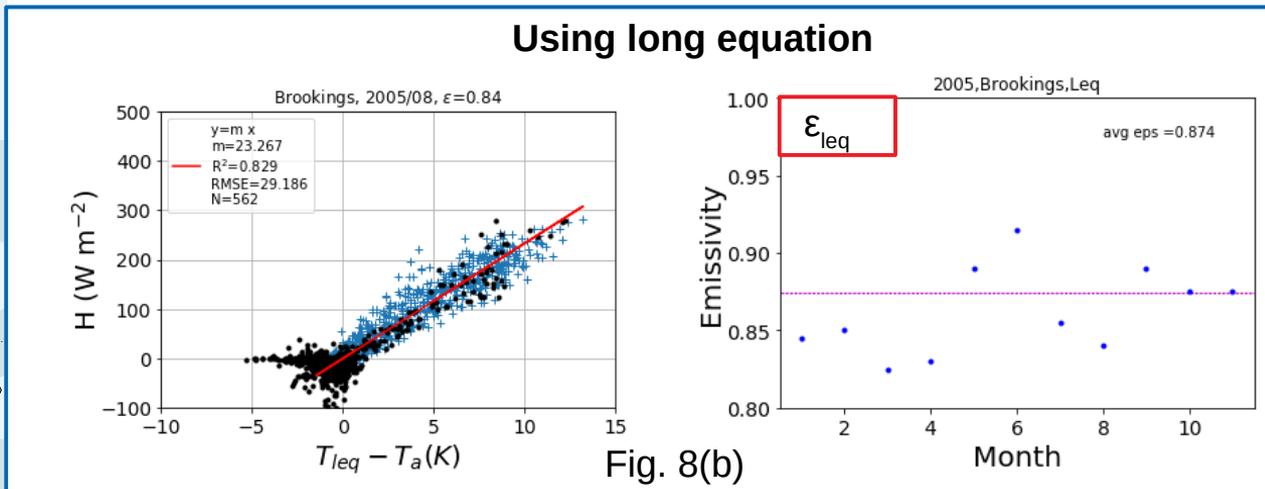

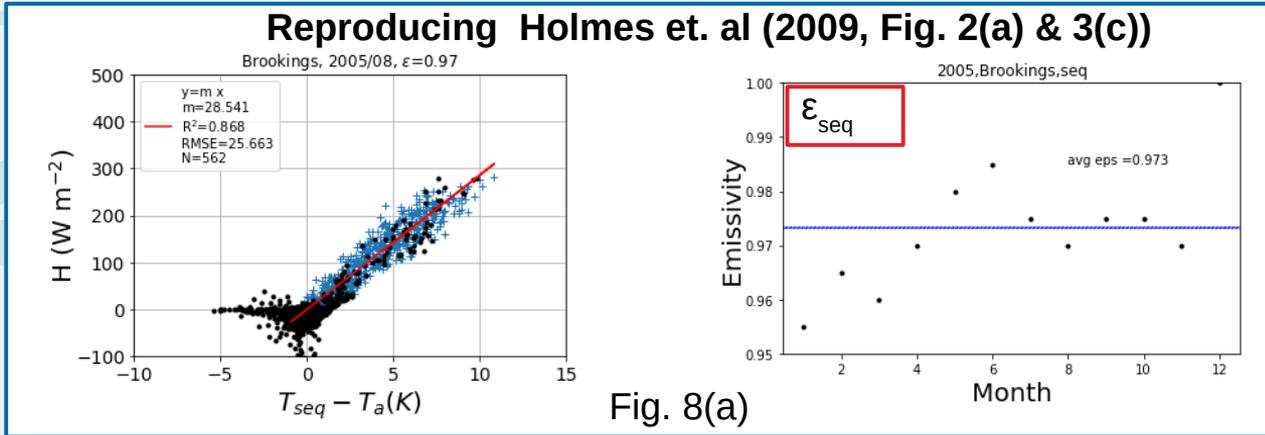

Fig. 7: Work flow for calculation of optimum emissivity ( $\epsilon_{opt}$ )

1. Introduction

  - 2.2 Validation
3. Objective 2
  - 3.1 Holmes approach
  - 3.2 Results
  - 3.3 Validation
4. Conclusions

# OPTIMIZED EMISSIVITY: SEQ & LEQ

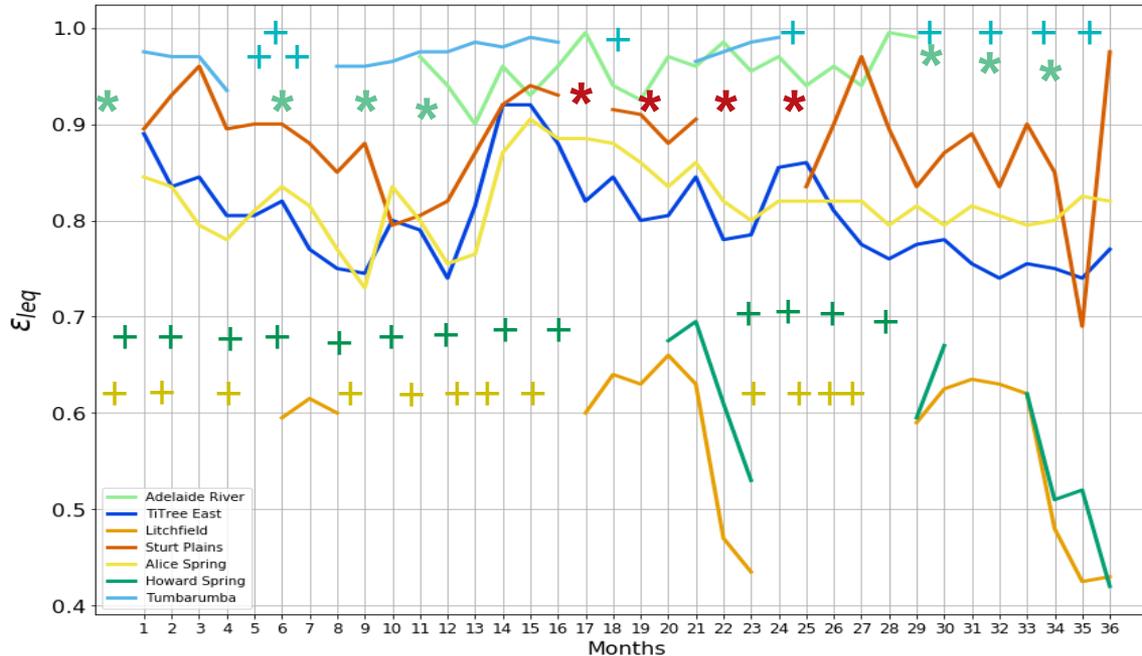

- 1. Introduction
  - 1.1 Background
  - 1.2 Objective
  - 1.3 Study sites
- 2. Objective 1
  - 2.1 Results
  - 2.2 Validation
- 3. Objective 2
  - 3.1 Holmes approach
  - 3.2 Results
  - 3.3 Validation
- 4. Conclusions

$\epsilon_{leq} < \epsilon_{seq}$

# OPTIMIZED EMISSIVITY: LEQ @ STUDY SITES:

- 1. Introduction
  - 1.1 Background
  - 1.2 Objective
  - 1.3 Study sites
- 2. Objective 1
  - 2.1 Results
  - 2.2 Validation
- 3. Objective 2
  - 3.1 Holmes approach
  - 3.2 Results
  - 3.3 Validation
- 4. Conclusions

$\epsilon_{leq}$  values are much lower than  $\epsilon_{seq}$  and  $\epsilon_{MODIS}$

Broken lines due to:  
 \* → Missing data  
 + →  $R^2(H vs \Delta T) < 0.5$

Fig. 9: Optimized emissivity values for three consecutive years at the study sites

# COMPARISON: PLOT SCALE OPTIMIZED LST WITH MODIS LST

- 1. Introduction
  - 1.1 Background
  - 1.2 Objective
  - 1.3 Study sites
- 2. Objective 1
  - 2.1 Results
  - 2.2 Validation
- 3. Objective 2
  - 3.1 Holmes approach
  - 3.2 Results
  - 3.3 Validation
- 4. Conclusions

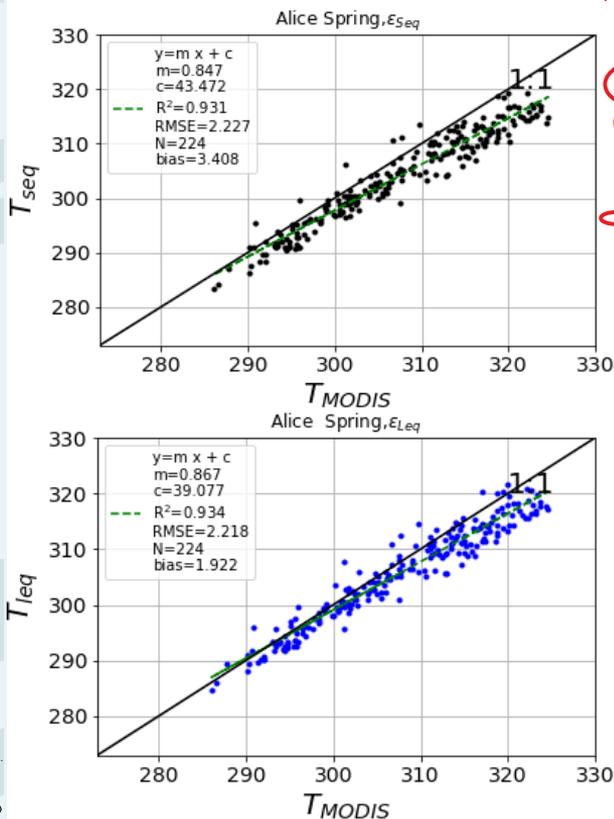

Fig. 9: Plot showing LST bias using  $\epsilon_{opt}$  @ Alice spring at MODIS measurement time

LST bias is reduced using optimized emissivity

$$(T_{MODIS} - T_{leq}) < (T_{MODIS} - T_{seq})$$

Table 3. LST bias &  $R^2$  values @ study sites using optimized emissivity

Site	Seq		Leq	
	$R^2$	Bias	$R^2$	Bias
Litchfield	0.40	4.41	0.41	2.57
Tumbarumba	0.82	2.27	0.84	2.10
Alice Springs	0.93	3.41	0.93	1.92
Howard Springs	0.21	4.78	0.22	2.47
Sturt Plains	0.81	3.00	0.82	1.91
Ti tree East	0.58	5.06	0.52	4.02
Adelaide River	0.61	0.35	0.24	2.93

# CONCLUSIONS:

- 1. Introduction
  - 1.1 Background
  - 1.2 Objective
  - 1.3 Study sites
- 2. Objective 1
  - 2.1 Results
  - 2.2 Validation
- 3. Objective 2
  - 3.1 Holmes approach
  - 3.2 Results
  - 3.3 Validation
- 4. Conclusions

- Plot-scale land surface temperature (LST) derived using MODIS emissivity is generally lower than MODIS LST 
- Short equation produces different results to long equation and therefore should not be used 
- Long equation is less sensitive to emissivity, therefore bias cannot easily be "corrected" by small changes in emissivity
  - bigger LST bias compared to MODIS 
  - lower optimized emissivity 
- Reduction in H vs DT bias leads to better match with LST from MODIS
