1. Introduction

- Due to **solar insolation**, **semiarid** landscapes experience differentiation in vegetation type and density on opposing hillslopes.
- Xeric and sparse vegetation on **equatorward** slopes while mesic and denser canopy exists at **poleward** slopes.
- The equatorward slopes are more prone to erosion due to **less vegetation** cover which causes the asymmetry of hillslopes over long timescales. It is measured by the **Hillslope Asymmetry Index** (HAI), (*Poulos et al., 2012*).
- However, there lies several limitations in *Poulos et al., 2012* such as existing tectonic controls, lack of the aspect-controlled vegetation differences, and no field sites in semiarid regions.
- The motivation behind this work is to investigate the relationship of HAI with geographic, ecologic, and climatological variables at a global scale by using observed and modeling studies.

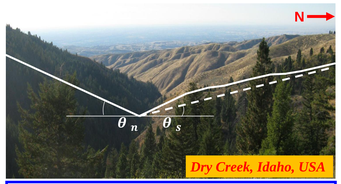

Figure 1. Dry Creek Foothills showing different vegetation pattern on north-facing and south-facing slopes (*Pierce and Poulos, 2013*)

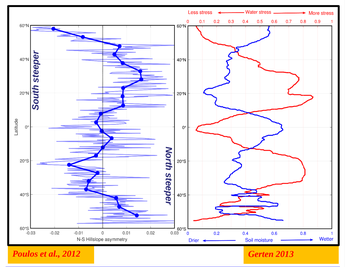

Figure 2. Latitudinal pattern of HAI, soil moisture and water limitation

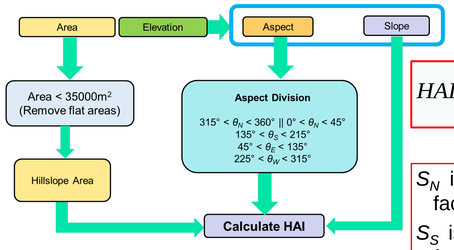
2. Data and Methods

- The entire study was conducted on two basis: observed catchments based on the previous literature and modeling study using a Landscape Evolution Model.
- For the real world scenarios, a total of 75 different catchments across 28 sites worldwide were selected for this study based on careful review of previous studies reporting the existence of pronounced aspect-induced differences on vegetation at opposing hillslopes (*Kumari et al., 2019*).
- The HAI is calculated by using 30-m resolution digital elevation models (DEMs) obtained from the United States Geological Survey (USGS) for all the 75 catchments.



$$HAI_{N-S} = \log_{10}\frac{med(S_N)}{med(S_S)}$$

S_N is slope (°) in North facing slopes (NFS)

S_S is slope (°) in South facing slopes (SFS)

3. Observation Studies to Understand Global Hillslope Asymmetry

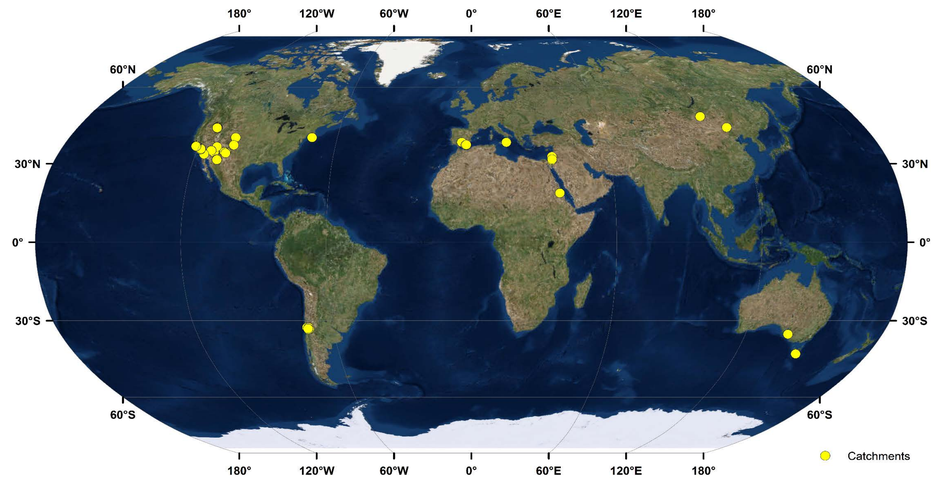

Figure 4. Location map for all the 75 catchments taken in this study in the Northern and the Southern Hemisphere

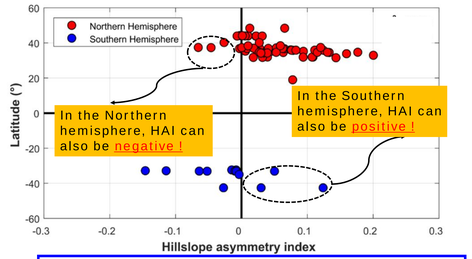

Figure 5. Latitudinal pattern of HAI observed in 75 catchments

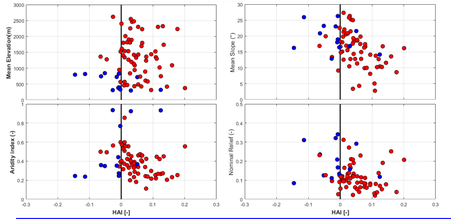

Figure 7. Observed analysis of factors affecting HAI in different catchments

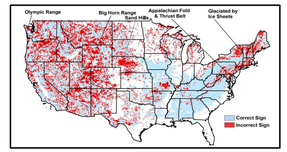

Pelletier et al., 2018

Figure 6. USA Map illustrating correct (+) and incorrect (-) signs of HAI

- In the Northern (Southern) Hemisphere, ~70% of the sites have HAI positive (negative). It implies that NFS (SFS) is steeper than SFS (NFS). However, there are few sites which shows reverse pattern. Similar reverse pattern are observed in *Pelletier et al., 2018*.
- Other factors like elevation, slope, aridity, and relief does not show much clear correlation with HAI.

4. Modelling Results to Understand Global Hillslope Asymmetry

- We used the **Channel-Hillslope Integrated Landscape Development model (CHILD)** landscape evolution model (LEM) coupled with a vegetation dynamics component.

Radiation balance: $R_n = (1-\alpha)R_{SW} + \left(\downarrow R_{LW} - \uparrow R_{LW}\right)$

Water balance: $nZ_r\frac{ds}{dt} = I(s) - ET(s) - D(s)$

Elevation: $\frac{\partial z}{\partial t} = U - \nabla q_{sd} - \nabla q_{sf}\left(q_w, V\right)$

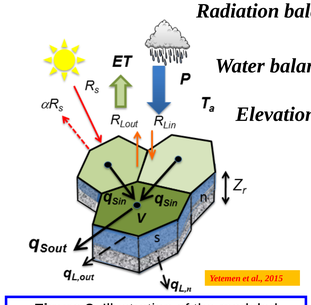

Figure 8. Illustration of the modeled variables in a Voronoi cell used in the CHILD

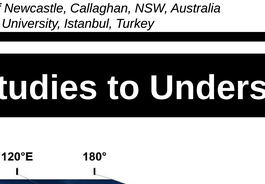

Figure 9. Synthetic domain used in the CHILD simulations

Model Setup

Dimensions	: 900 m by 900 m
Grid size	: 20 m
Initial Max Height	: 60 m
Simulation duration	: 700,000 years
Outlet	: one side open-boundary
Uplift	: No uplift, 0.05 mm/y, and 0.1 mm/y

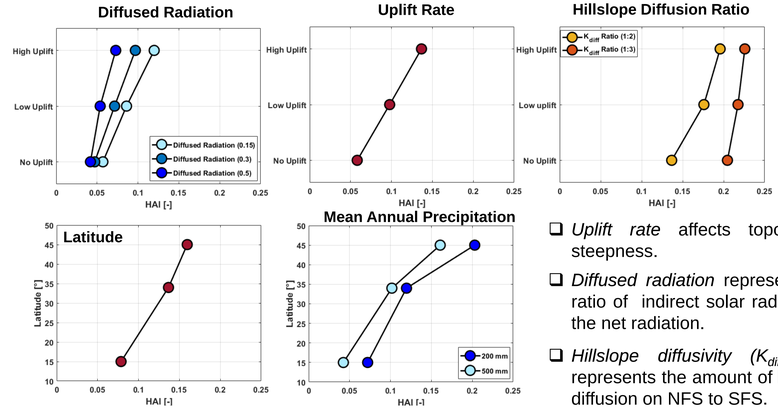

Figure 10. Modeling results for factors affecting HAI using CHILD LEM

- *Uplift rate* affects topographic steepness.
- *Diffused radiation* represents the ratio of indirect solar radiation to the net radiation.
- *Hillslope diffusivity (K_{diff}) ratio* represents the amount of hillslope diffusion on NFS to SFS.

5. Conclusion

- HAI increases towards the higher latitude due to enhanced variation in incoming solar radiation on opposing aspects; hence, there is a positive correlation between HAI and latitude, which is not much enhanced in the field site analysis because they lie mostly at same latitudes.
- The findings from the CHILD modeling study suggest that HAI increases with increase in uplift (function of elevation and slope), increase in K_{diff} ratio (when SFS has higher K_{diff}); while decreases with increase in precipitation and diffused radiation.
