The Münsterdorf sinkhole cluster: Void origin and mechanical failure

Georg Kaufmann\textsuperscript{1}, Douchko Romanov\textsuperscript{1}, Ulrike Werban\textsuperscript{2} & Thomas Vienken\textsuperscript{2}

\textsuperscript{1} Freie Universität Berlin, Department of Geosciences, Geophysics Section, Berlin, Germany
\textsuperscript{2} Department Monitoring- und Erkundungstechnologien, Helmholtz-Zentrum für Umweltforschung - UFZ, Leipzig, Germany
Location

- North of **Hamburg**.
- Village of **Münsterdorf** (grey dot).
- **Sports field** (blue dots).
- **Sinkholes** (blue dots).
- **Chalk** in 20 m depth (red contour lines).
- Large **open-pit mines** (white areas).

Data: SRTM; Chalk depth: R. Kirsch
(from: Kaufmann et al., 2018, Fig. 2).
Sinkholes

- Sinkhole cluster
- Roughly **one every year**.
- **Size** around 2-3 m in diameter and 2-5 m deep.
- Expose **unconsolidated material**:  
  - **Peri-glacial sand**  
  - **Glacial till**
- Chalk in 20 m depth.

Data: SRTM; Chalk depth: R. Kirsch (from: Kaufmann et al., 2018, Fig. 2).
Geophysical field work

Methods

- Gravity
- Electrical resistivity tomography
- Georadar
- Direct-push measurements

Reveals change in sub-surface structure:

- North: Shallow glacial till
- South: Deeper glacial till

Data: SRTM; Chalk depth: R. Kirsch (from: Kaufmann et al., 2018, Fig. 7).
Failure model

- **Yade** discrete-element model.
- Layers with **different** mechanical properties.
- Mechanical properties derived from **direct-push measurements**.
- Model indicates sinkhole collapse, when . . .
  - . . . Void has formed in around 20 m depth.
  - . . . Buoyant support in void (partially) reduced.

(from: Kaufmann et al., 2020, prepared).
Hypothetical model

- Chalk in 20 m depth **karstified**.
- **Meter-size voids** in phreatic zone.
- **Groundwater level** originally in 2-3 m depth.
- Glacial till and peri-glacial sands (semi-)stable above voids.
- **Groundwater drop** due to pumping in large open-pit mines nearby triggers sinkholes!

From: Kaufmann et al. (2018), Fig. 11.
Conclusions

- Sinkholes on sports field start with abrupt onset around 2004.
- Sinkholes occur roughly once per year.
- Sinkholes are 2-3 m in diameter and 2-5 m deep.
- Initial void likely in chalk in around 20 m depth.
- Fall in groundwater level due to open-pit mining.
- Loss of buoyant support can induce instability of strong layers.
