

Assessment of the empirical matched field processing algorithm for autonomous tracking of aftershock sequences

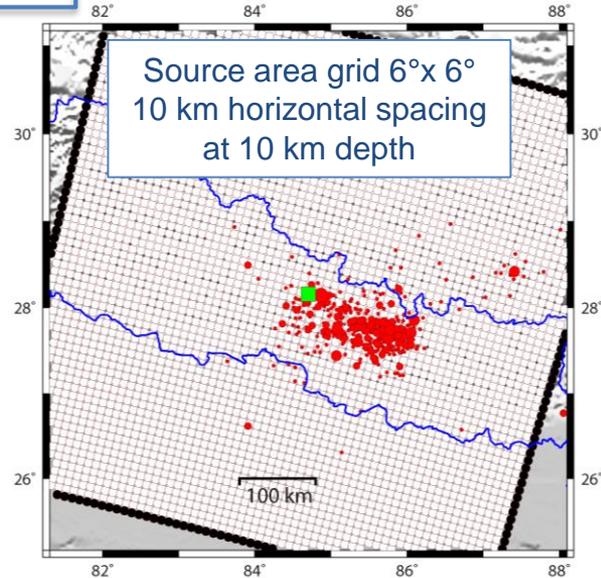

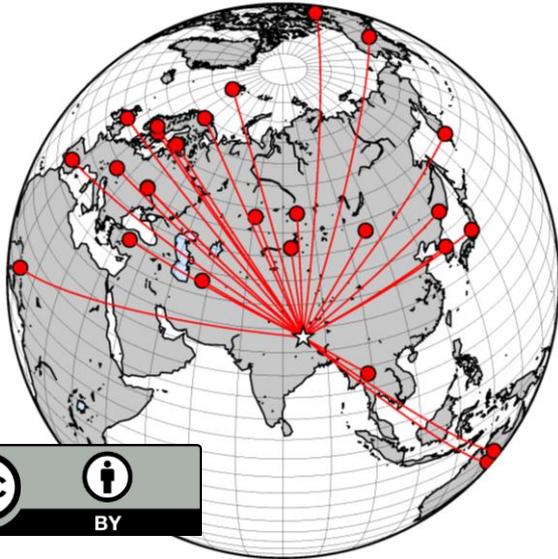

Overview

- **Background:**
Reducing work load of analysts during processing of aftershock sequences of large earthquakes
- **Concept:**
Use signals from the main event as templates for automatic processing of aftershocks and other recurring events
- **Method:**
Empirical Matched Field (EMF) detector
- **Application presented here:**
Nepal: April 25, 2015 (Mw = 7.8)
(processing of 7 days following the main event)
- **Evaluation:**
Comparison with IDC event bulletins: REB (reviewed) and SEL3 (automatic)

How this works:

- Pick main shock on all arrays to define steering vectors for EMF
- Detect signals using EMF statistic
- Get accurate phase onsets
- Estimate back-azimuth & slowness

Construct grid system
Associate arrivals

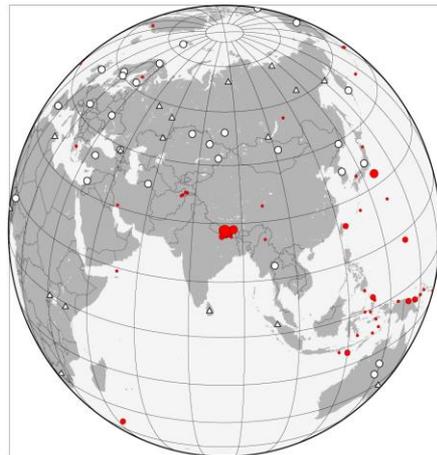

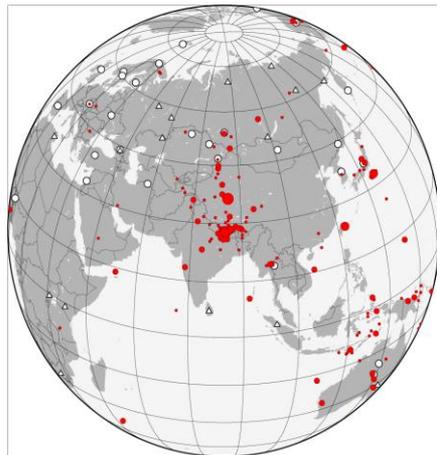

Aftershock event
bulletin

Relocations
from BayesLoc

SEL3 – REB, first 24 hours

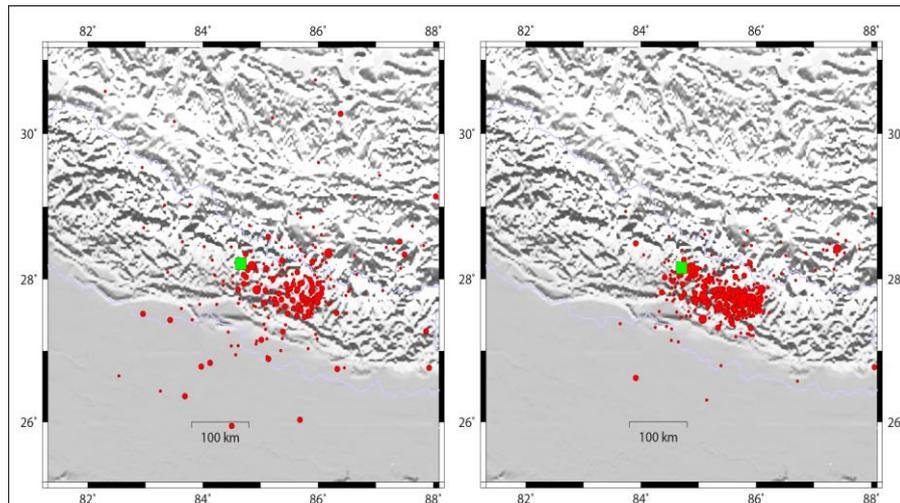

SEL3 – REB, 7 days

SL3 fully automatic bulletin

REB analyst-reviewed bulletin

2015-115:06.10 - 2015-116:06.10 UT (April 25 - April 26, 2015)

SL3 fully automatic bulletin

REB analyst-reviewed bulletin

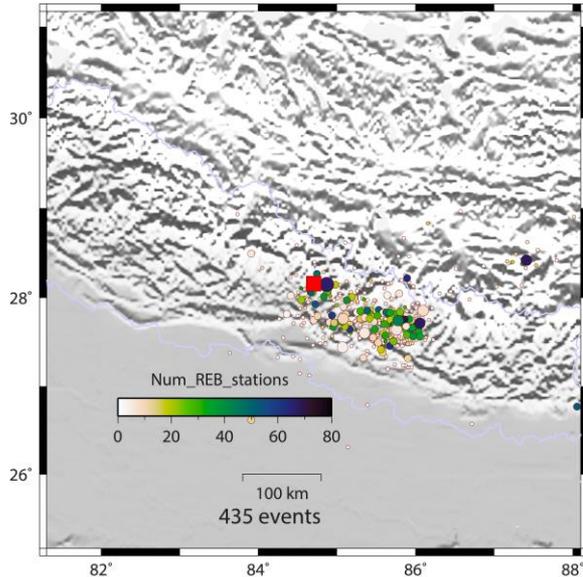

2015-115:06.10 - 2015-122:06.10 UT (April 25 - May 2, 2015)

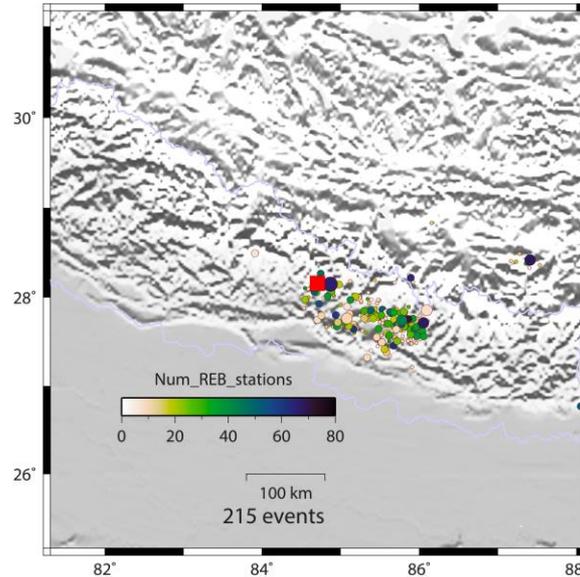

EMF evaluation results

Nepal: 215 (49.4%) of 435 REB events found by EMF
Tolerances: 150 km, 30 seconds

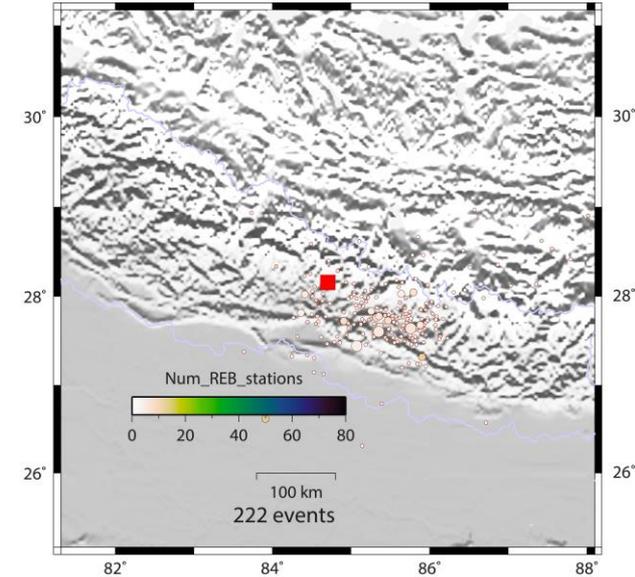

Events in REB

REB events found by EMF

REB events NOT found by EMF

All low number of defining stations!

EMF evaluation results

Nepal: 215 (49.4%) of 435 REB events found by EMF
Tolerances: 150 km, 30 seconds

#REB events inside box	435	
#matching EMF events	215	49.4%
#matching SEL3 events (same eventID)	284	65.3%
#matching SEL3 events (same eventID and within box)	232	53.3%
#matching REB, SEL3 and EMF	194	44.6%
#EMF events not matching any REB event	40	To be addressed

EMF events not matching any REB event

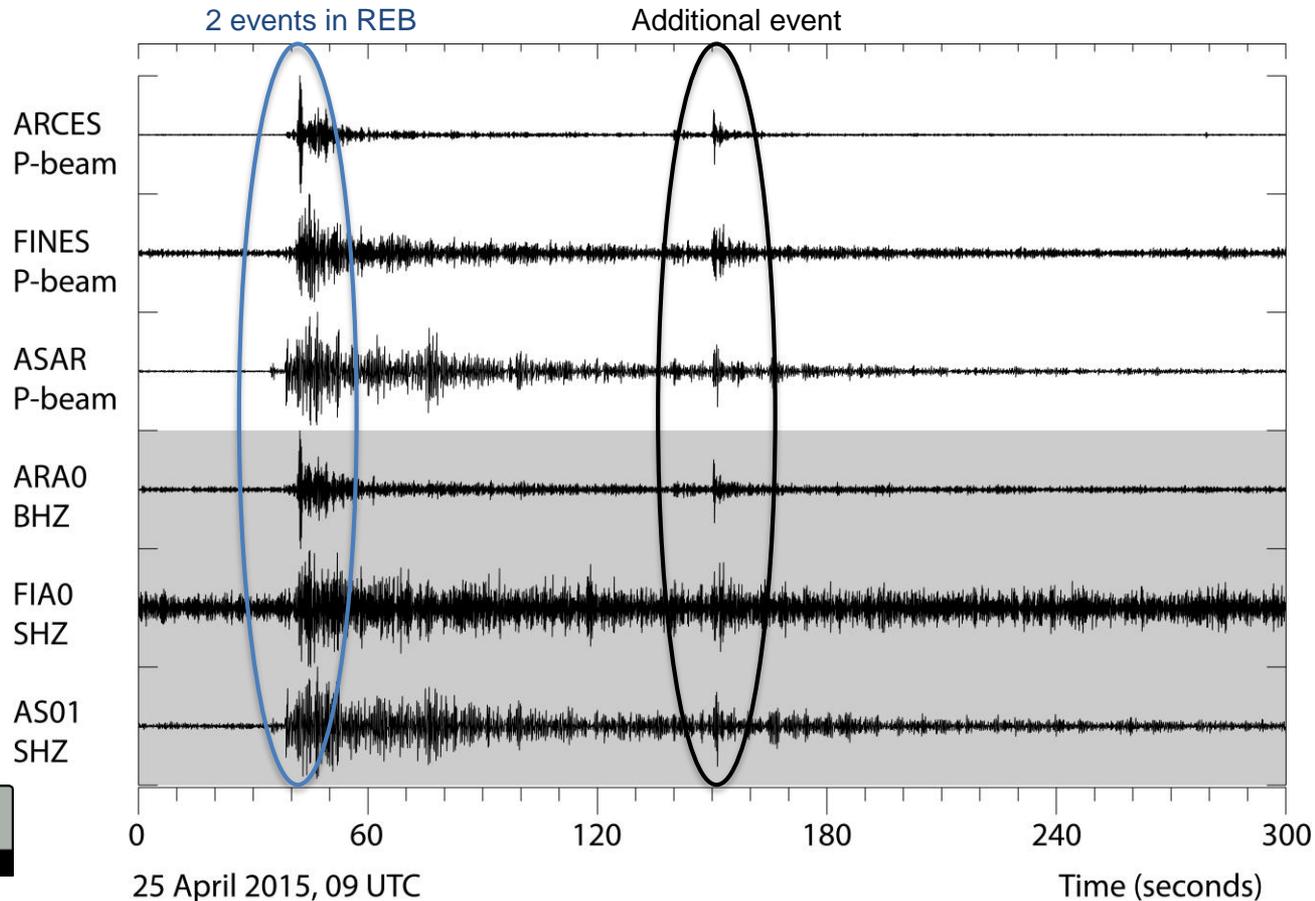

Events with only 4 station detections, split events, additional event

Origin time	#phases	Latitude	Longitude

EMF events not matching any REB event

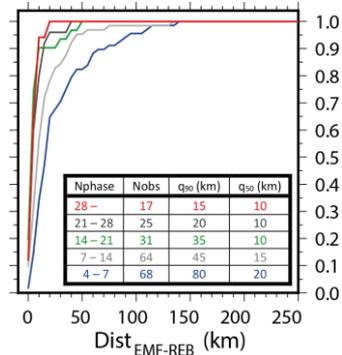

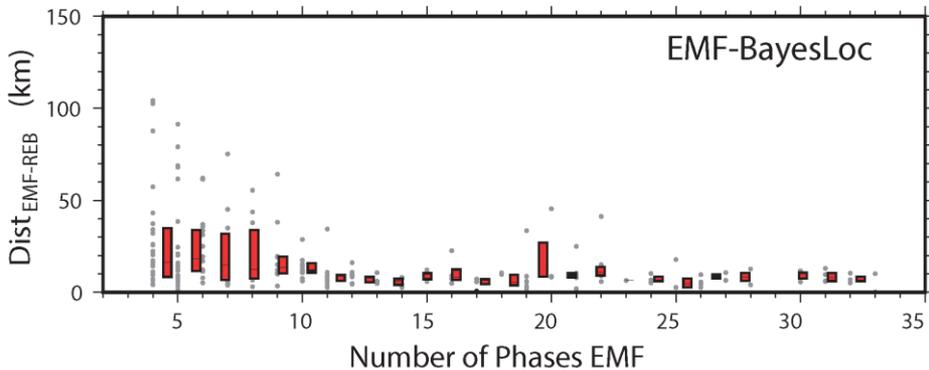

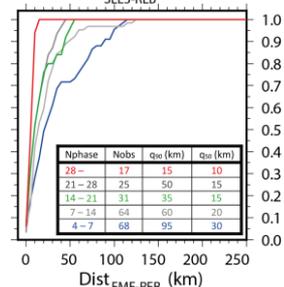

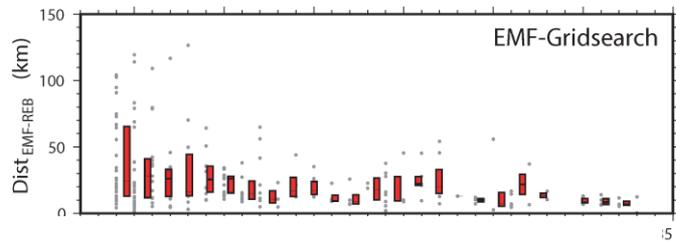

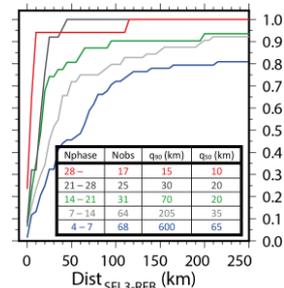

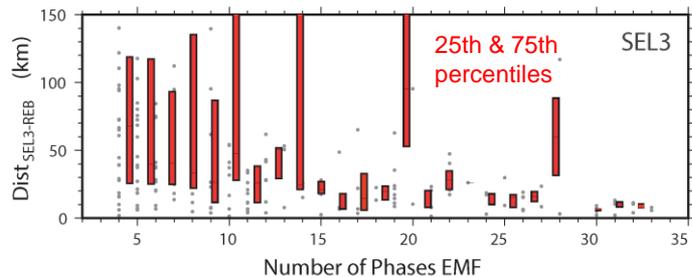

Events with only 4 station detections, split events, additional event

EMF evaluation results

Location differences of SEL3 and EMF relative to the REB

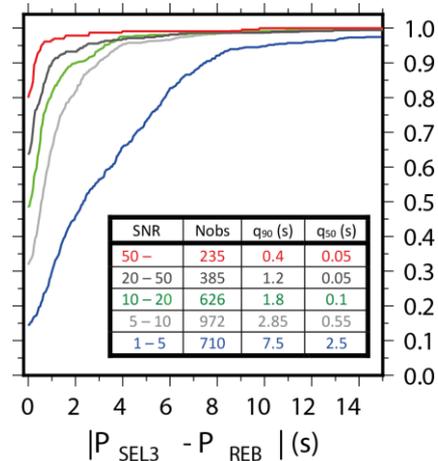

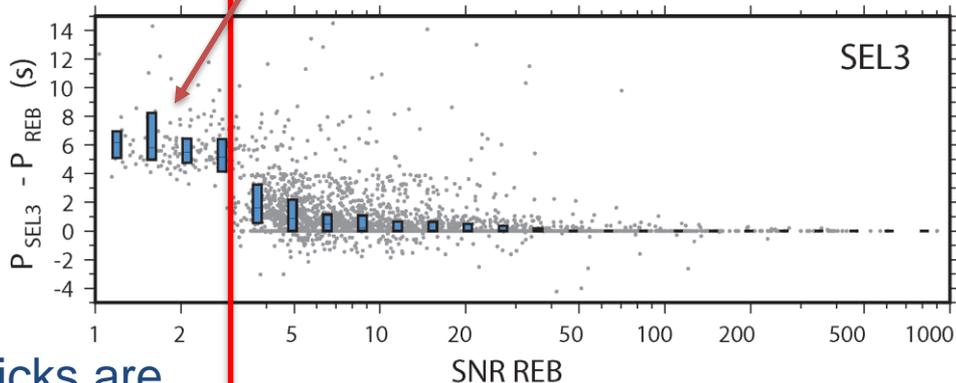

(1) EMF events are closer to REB events

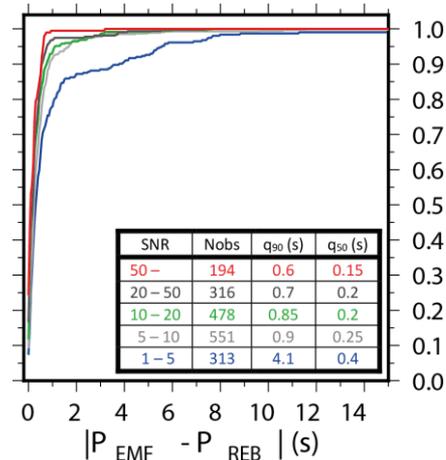

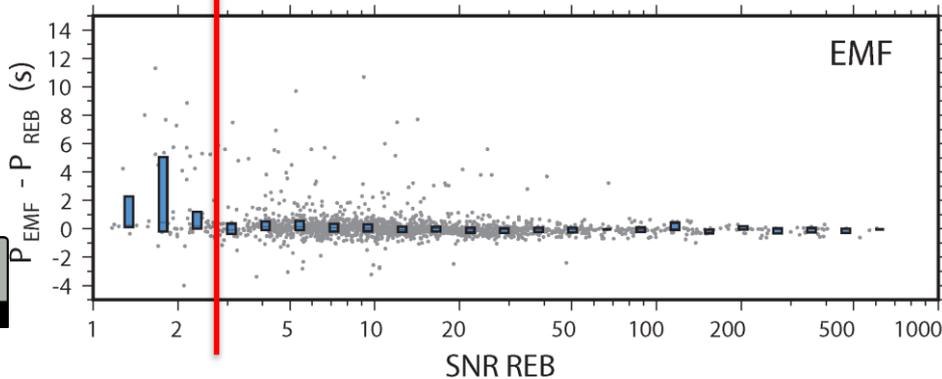

EMF evaluation results

Differences of SEL3 and EMF arrival times relative to REB

SEL3 has no SNR<3: These are phase IDs of later phases reassigned by the analyst to weak first arrival

(2) EMF picks are closer to REB picks

Summary

- For the NEPAL earthquake sequence false event definitions are of minor concern
- The automatic EMF-based processing algorithm is picking up 50-60% of the events found in the REB. Those not found have low number of associated arrivals in REB.
- For matched events, the EMF-based processing algorithm is performing significantly better than the current automatic processing algorithms used at CTBTO, as reported in the SEL3. This applies both to location accuracy and onset time estimates.
- Application of the EMF-based processing methodology is likely to provide a more accurate starting point for the human analyst, and thus reduce the labor burden.
- Other aftershock sequences are under investigation.
