

# The distribution and saturation of water vapor with ACS/TGO for first Martian year of observations

Anna Fedorova, Franck Montmessin, Oleg Korablev, Mikhail Luginin,  
Alexander Trokhimovskiy, Denis Belyaev, Nikolay I. Ignatiev, Franck Lefèvre,  
Juan Alday, Kevin Olsen, Jean-Loup Bertaux, Ehouarn Millour, Anni  
Määttänen, Alexey Shakun, Alexey V. Grigoriev, Andrey Patrakeev, Svyatoslav  
Korsa, Colin F. Wilson and the ACS team

## Introduction

# Vertical distribution of H<sub>2</sub>O on Mars

□ potentially driven by many processes

- microphysics
- chemistry involved

□ diagnostics of the interaction with the CO<sub>2</sub> and dust climatic cycles

□ Access of water to high altitude  
Important for the understanding of the escape process of water on Mars

□ Direct measurements of hygropause variations

□ supersaturation and an access of water above the hygropause in the aphelion season

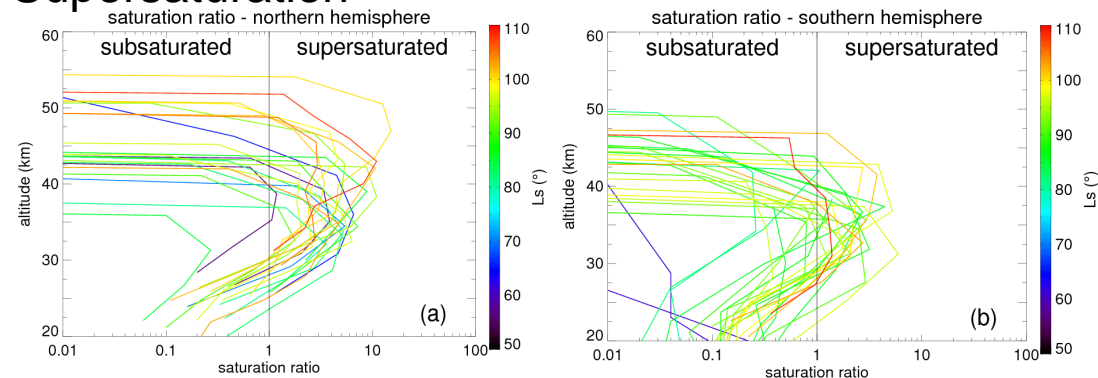

*Chaffin et al., 2017*

## Saturation altitude

*Trokhimovsky et al., 2015*

## Supersaturation

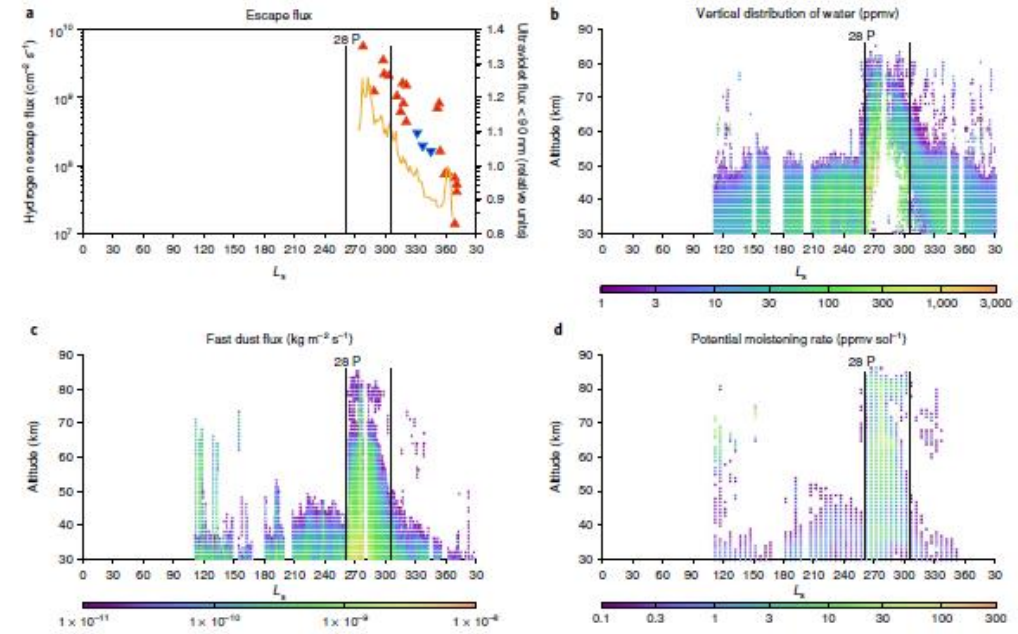

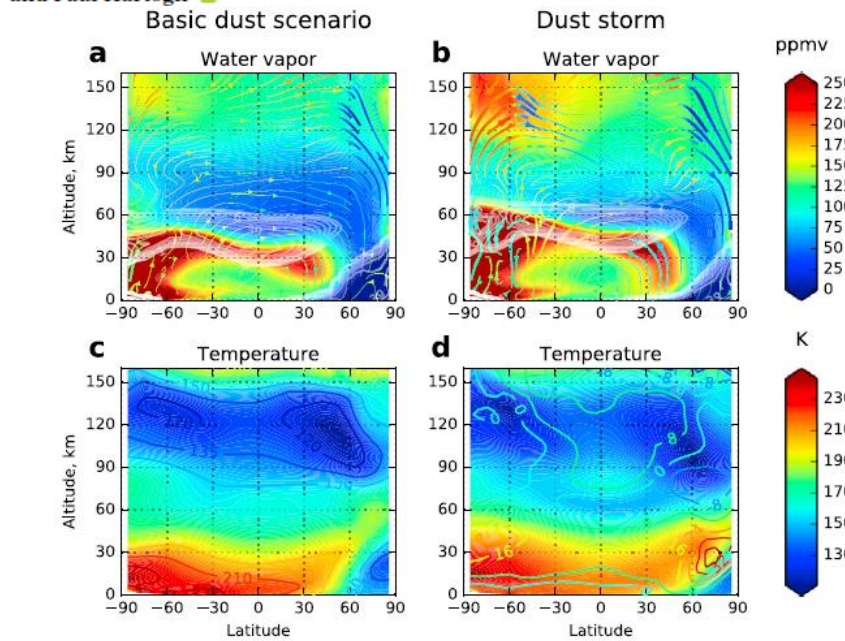

*Maltagliati et al., 2011*

SPICAM long-term observations MY28-33

The 2016 mission consists of a Trace Gas Orbiter (TGO) with four science instruments. It also included an EDL Demonstrator Module (EDM=Schiaparelli). Launched 14.03.2016, in orbit since 19.10.2016, aerobraking completed ~10.03.2018

### NOMAD

High-resolution occultation and nadir spectrometers

*Atmospheric composition (CH<sub>4</sub>, O<sub>3</sub>, trace species, isotopes) dust, clouds, P&T profiles*

UVIS (0.20 – 0.65 μm) λ/Δλ ~250	SO	Limb	Nadir
IR (2.3 – 3.8 μm) λ/Δλ ~10,000	SO	Limb	Nadir
IR (2.3 – 4.3 μm) λ/Δλ ~20,000	SO		

### CaSSIS

High-resolution, stereo camera

*Mapping of sources Landing site selection*

### ACS

Suite of 3 high-resolution spectrometers

*Atmospheric chemistry, aerosols, surface T, structure*

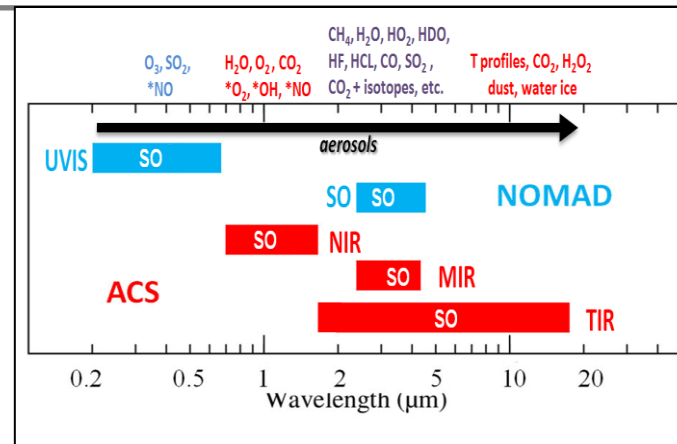

Near IR (0.7 – 1.7 μm) λ/Δλ ~20,000	SO	Limb	Nadir
IR (Fourier, 2.5 – 25 μm) λ/Δλ ~4,000 (SO)/500 (N)	SO		Nadir
IR (2.3 – 4.3 μm) λ/Δλ ~20,000	SO		

### FREND

Collimated neutron detector

*Mapping of subsurface water and hydrated minerals*

# ACS

Atmospheric Chemistry Suite

## Solar Occultation is the main point of the TGO atmospheric science

High sensitivity

When we observe the direct sun light through the atmosphere of Mars the intensity is  $10^6$  times more than observing the Mars surface. The air mass factor at the limb is  $\sim 30$

For 12 TGO orbits per day 24 occultations per day is possible

- 10 occultations per day for with ACS driven pointing (trace gas study+climatology)
- 14 occultations per day with NOMAD driven pointing

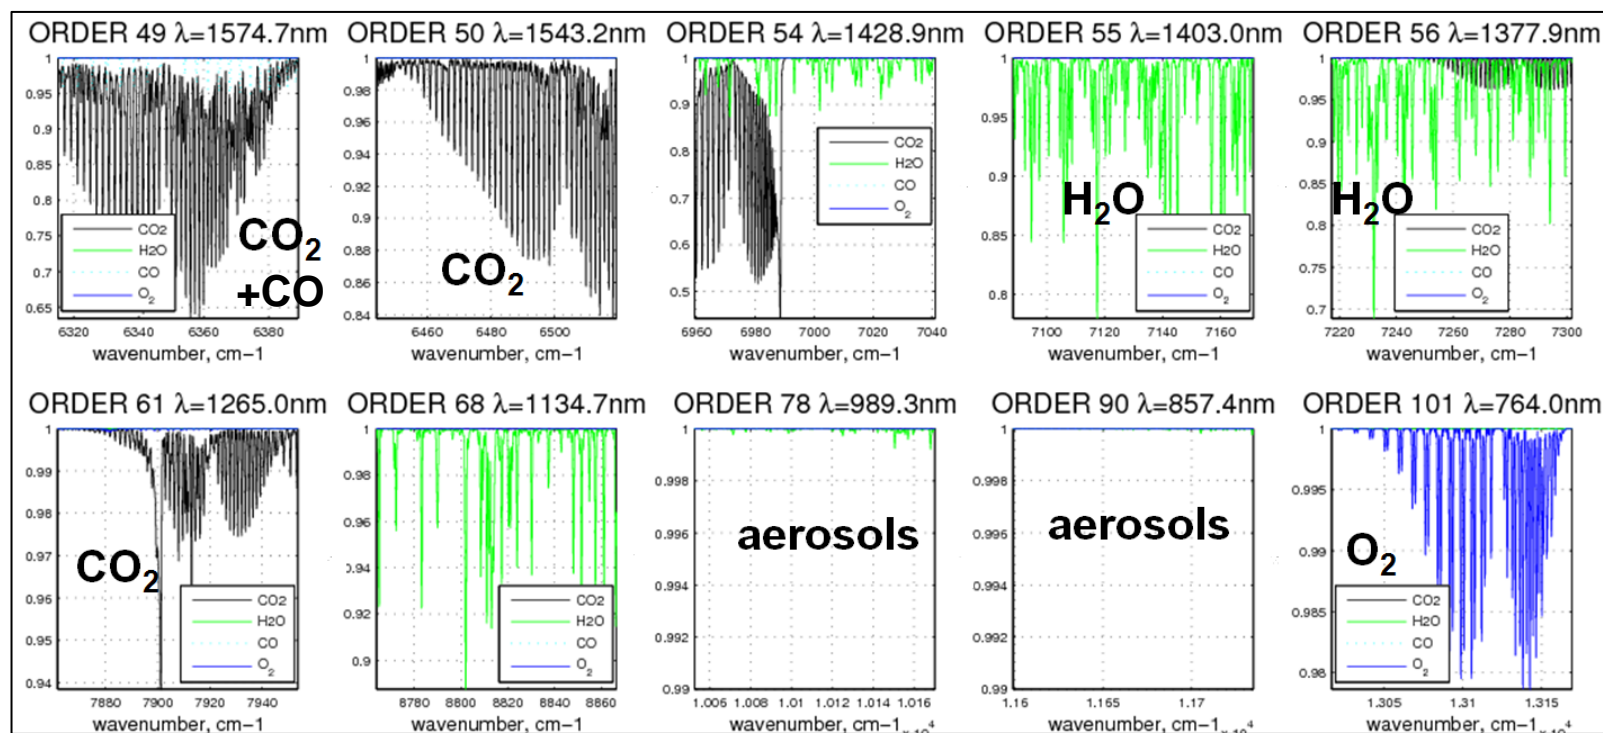

## ACS NIR occultations observations

- Spectral range: 0.73 – 1.6  $\mu\text{m}$  (not covered by other TGO instruments)
- Spectral resolving power  $\lambda/\Delta\lambda$ : ~25 000

➤ Standard planned measurement sequence of NIR in solar occultation includes 10 diffraction orders in the range of 0.76 -1.58  $\mu\text{m}$  ( $\text{H}_2\text{O}$ ,  $\text{CO}_2$ , aerosols + Novel  $\text{O}_2$ ).

- ACS NIR has a very flexible setup of observation parameters. Data volume with the highest data rate (vertical resolution 0.7 km)
- To decrease the altitude step it is possible to decrease number of orders to 6 (excluding two  $\text{CO}_2$  and two  $\text{H}_2\text{O}$  orders)

# Sensitivity to measure H<sub>2</sub>O for NIR for different dust conditions

**For ACS-NIR:**  $\lambda/\Delta\lambda=25000$  and  $SNR=4000$  for an integration time of 1 ms and with 32 accumulations.

## CO<sub>2</sub> and H<sub>2</sub>O retrieval

### Direct model:

- Spectroscopy: HITRAN2016 (Gordon et al., 2017):
  - ❑ H<sub>2</sub>O with air broadening multiplied by 1.7
  - ❑ CO<sub>2</sub> with self broadening
- MCD 5.3 “climatology” temperature-pressure profiles as an initial assumption (*for CO<sub>2</sub>*)
- Temperature and pressure from NIR CO<sub>2</sub> for the water retrieval:
  - ❑ First step: independent T and P retrieval
  - ❑ second step: hydrostatic assumption
- The order overlapping due to far wings of the AOTF function is included
- Spectral resolution is varied with a pixel and the spectral range of an order

### Inverse model:

- Based on SPICAM IR algorithms (Fedorova et al., 2009; 2018; Maltagliati et al., 2013)
- The whole profile is retrieved at the same time using Levenberg–Marquardt iterative algorithm (Levenberg, 1944; Marquardt, 1963).
- The Tikhonov regularization is applied a posteriori, customary for vertical inversions in order to smooth the profile and minimize the errors (Ceccherini et al., 2005, 2007).
- The uncertainties in the retrieved parameters are given by the covariance matrix of the solution errors.

ACS NIR occultations

retrieval

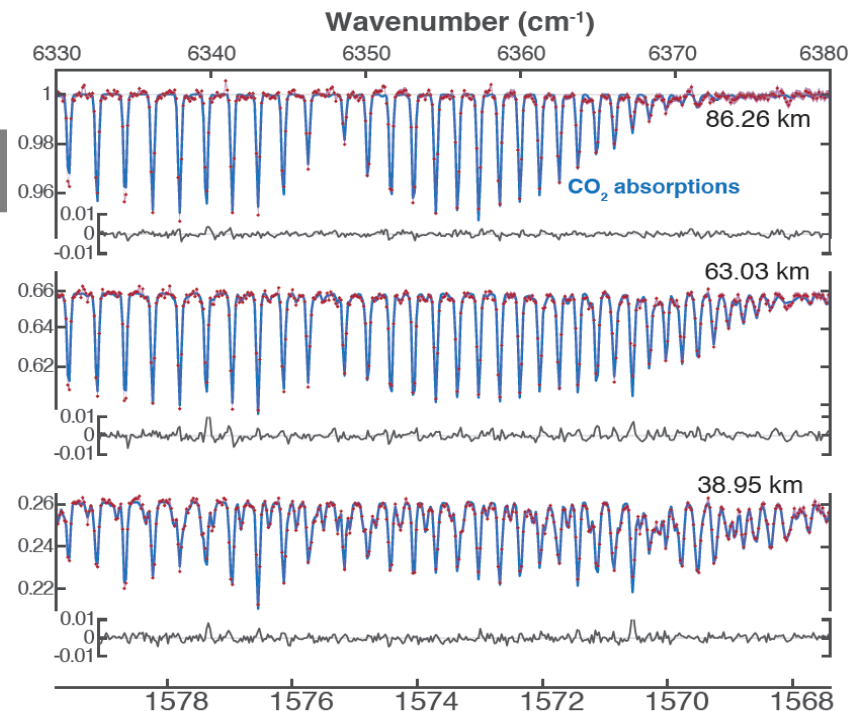

# Examples of H<sub>2</sub>O spectra

## 1.38 $\mu\text{m}$

*H<sub>2</sub>O can be retrieved using order 56. But we need temperature and pressure profiles*

# CO<sub>2</sub> retrieval

**Order 49** – good sensitivity to temperature, possibility to retrieve temperature-pressure profiles using iterative algorithm

Temperature  
retrieved  
simultaneously  
from NIR CO<sub>2</sub>  
bands (1.57 μm)

Before 2018A

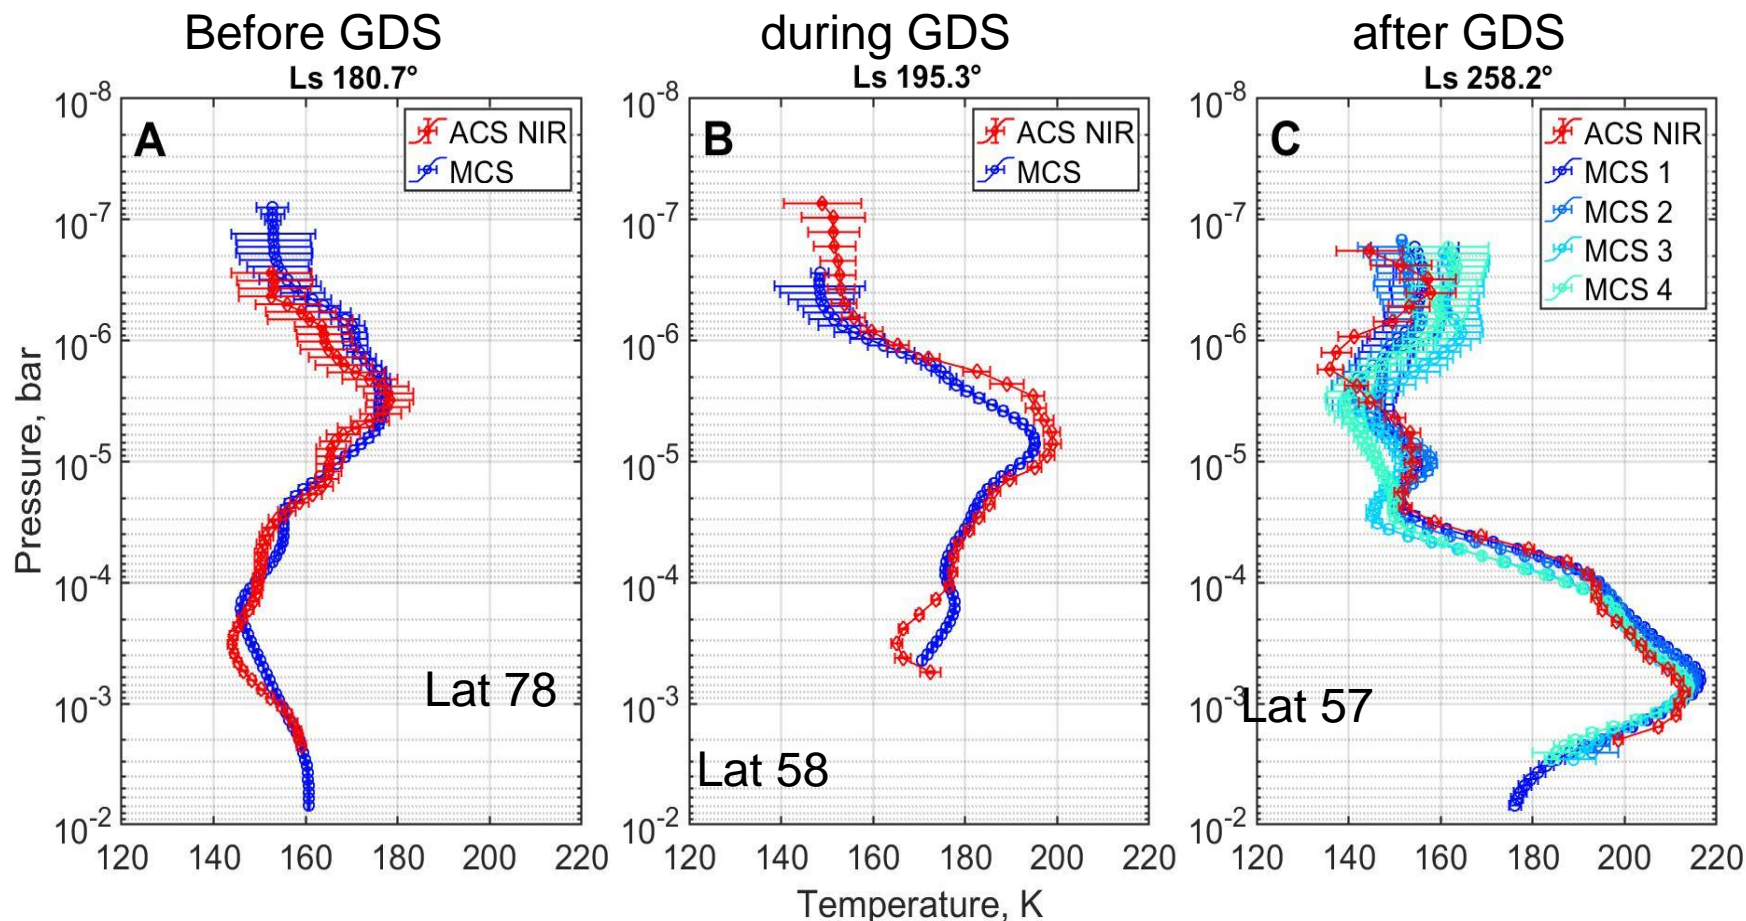

During 2018A

- Temperature (and density) underestimated by models
- Too much water v.m.r. with a model atmospheric profile

# Comparison of temperature with MCS/MRO

applying criteria on collocation (within  $\pm 1^\circ$  latitude and longitude)  
local time (2 hours) and season (within  $0.5^\circ$  of  $Ls$ )

# SPICAM/MEX: Detection of water vapor supersaturation in the middle atmosphere in MY29 (Maltagliati et al., 2011)

- NIR temperature + H<sub>2</sub>O = saturation ratio

Distribution of Mars Water Saturation Ratio ( $L_s=60-140^\circ$ )

a LMDGCM (left) and CRISM (right) Water Saturation Ratios

CRISM/MRO  
Indirect observations  
from the oxygen dayglow  
(Clancy et al., 2017)

Saturation ratio  
 $S = p_{\text{H}_2\text{O}}/e_s$

$$\log e_s = 2.07023 - 0.00320991T - 2484.896/T + 3.56654 \times \log T \quad (2)$$

where  $e_s$  is the saturation vapor pressure in mbar and  $T$  the temperature in Kelvin.

To distinguish water ice and dust: TIRVIM and MIR observations in 3  $\mu\text{m}$  band

## TIRVIM, Fourier

- Spectral range 1.7 – 17  $\mu$  (580–5800  $\text{cm}^{-1}$ )
- $\Delta\nu \sim 0.13 \text{ cm}^{-1}$  (Sun), 0.8  $\text{cm}^{-1}$  (Mars)
- Operation modes: Nadir and Solar Occultation
- FOV:  $\varnothing 2.5^\circ$

## MIR, echelle+cross-dispersion

- Spectral range 2.3 – 4.2  $\mu$
- $\lambda/\Delta\lambda \sim 50\,000$
- Operation modes: Solar Occultation
- FOV:  $0.23^\circ \times 0.02^\circ$

- Joint analysis of ACS NIR, MIR and TIRVIM data from April 2018 to March 2019 ( $L_s=163-355^\circ$ ) at the morning and evening terminator and ACS NIR up to Nov 2019
- NIR provides simultaneous measurements of:
  - ❑ **CO<sub>2</sub> band at 1.56  $\mu\text{m}$  (order 49)** - temperature-pressure profiles (0-110 km)
  - ❑ **H<sub>2</sub>O band at 1.38  $\mu\text{m}$  (order 56)** - vertical profiles in the low atmosphere (0-100 km)
- TIRVIM and MIR provide H<sub>2</sub>O ice near 3  $\mu\text{m}$  and dust extinctions
- Main results for H<sub>2</sub>O:
  - ❑ Atmospheric heating during the dust events (expected)
  - ❑ High altitude water during the dust events  $L_s=193-240$  (global) and  $L_s=220-235$  (regional)
  - ❑ High-altitude water during the summer in the southern hemisphere  $L_s=250-290$
  - ❑ **Supersaturation region has been observed:**
    - ✓ In low atmosphere 20-40km  $L_s<190$  and  $L_s>335$  and  $L_s=0-120$
    - ✓ In the upper atmosphere  $> 70\text{km}$   $L_s=200-300$  in both hemispheres
    - ✓ In the middle atmosphere at 50 km during the southern summer
  - ❑ **Supersaturation of water occurs even in the presence of clouds**
