Conclusions

- In the arid and semi-arid climate of the Loess Plateau region, severe long-term erosion has resulted in its hilly, gully eroded landscape.
- The ecological environment of the Loess Plateau Gully is fragile and soil erosion is dominated by hydraulic and gravity erosion.

**The incidence of erosion in areas with well-developed vegetation is relatively low and there is no substitute for the role of vegetation in soil erosion control.**

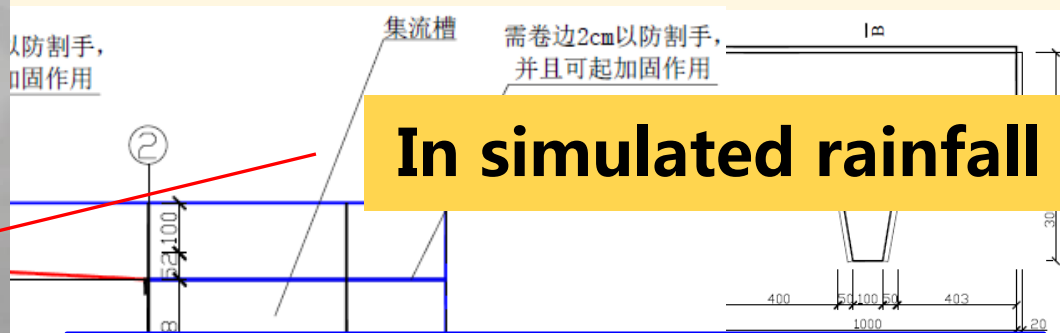

- The presence of plant roots in the soil increases the cohesion of the soil and thus the shear strength of the soil.
- Studies have shown that the root systems of different vegetation types have different abilities to enhance soil erosion resistance, with trees having a significantly stronger effect on soil erosion resistance than shrubs, and herbs being the weakest

**On the basis of the analysis of different working conditions, the effect of the root system of Yaoshuo Pine and Ziziacia on the shear strength and hardness of the soil is evaluated to reveal the mechanism of their soil and water conservation effects.**

# Test set-ups

## Test rainfall devices

**In simulated rainfall**

The rainfall nozzle is a rotating jet nozzle rainfall height of 5.5m, the rain screen covers an effective range of approximately 5m diameter circular surface.

Sampling site design

# 1. Influence of *Pinus tabuliformis* and *Amorpha fruticosa* on soil shear strength

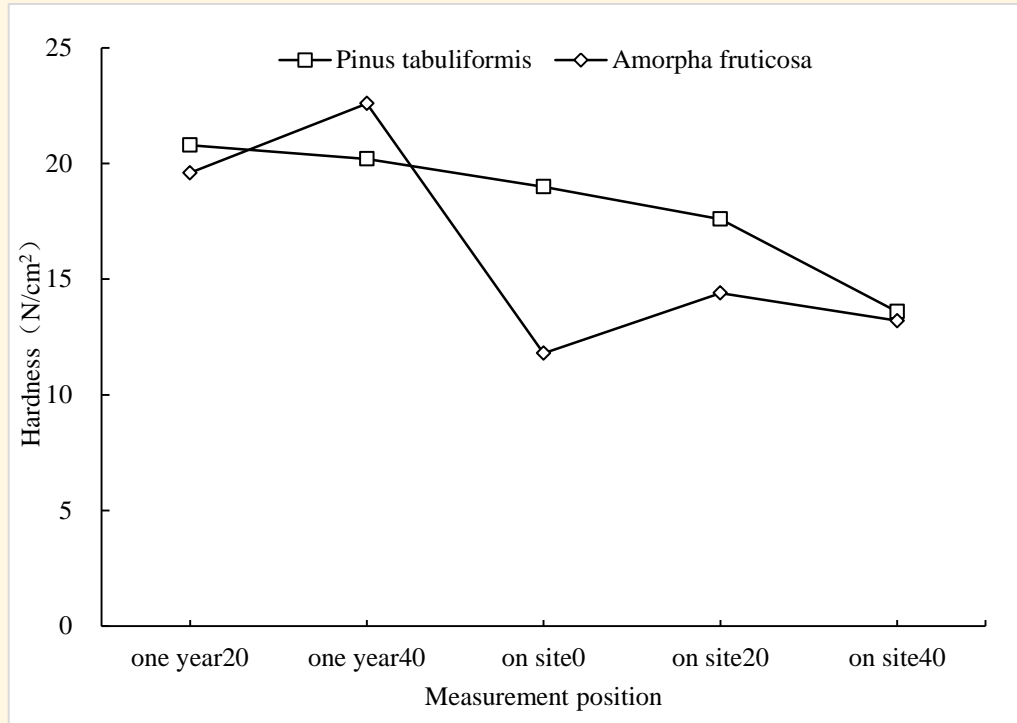

At a soil depth of 20 cm, the reinforcing soil effect of transplanted one-year *Amorpha fruticosa* roots was more significant than that of transplanted one-year *Pinus tabuliformis*, while the opposite was true for in situ transplants.

At a soil depth of 40 cm, the soil consolidation effect of transplanted one-year *Amorpha fruticosa* roots was more significant than that of transplanted one-year *Pinus tabuliformis*, while the soil consolidation ability of field transplanted vegetation *Amorpha fruticosa* was stronger than that of *Pinus tabuliformis*.

## 2. Influence of *Pinus tabuliformis* and *Amorpha fruticosa* on soil hardness

At a soil depth of 20 cm, the effect of *Pinus tabuliformis* on soil erosion resistance was higher than that of *Amorpha fruticosa* at most locations.

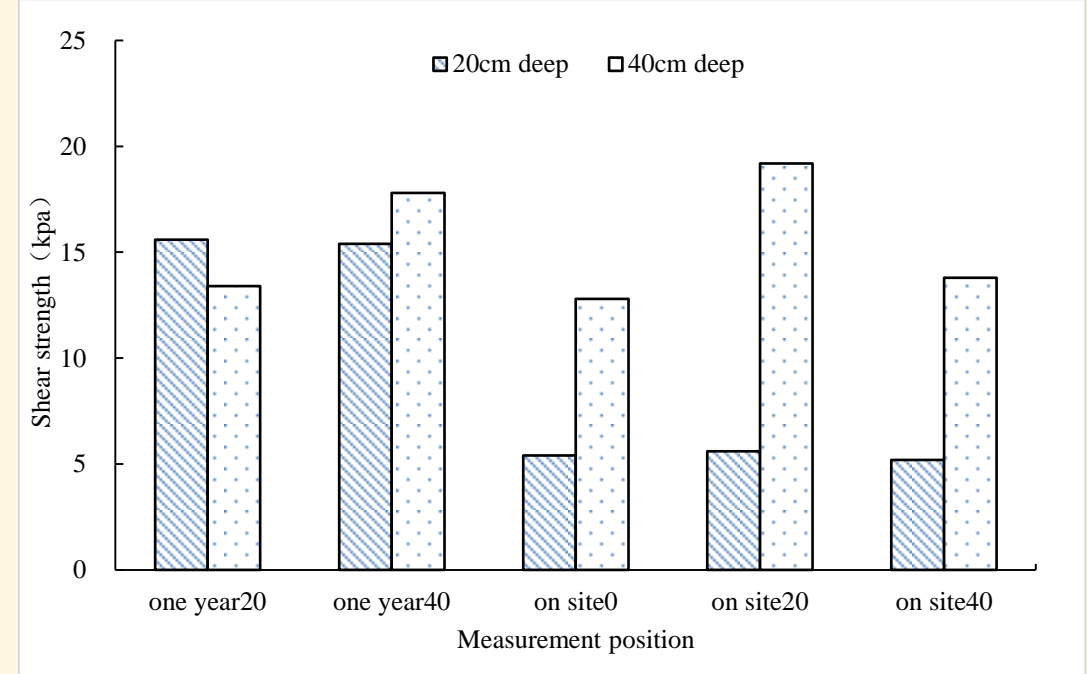

At a soil depth of 40 cm, the erosion resistance of the roots of the *Amorpha fruticosa* was significantly higher than that of the *Pinus tabuliformis* at most locations.

### 3. Influence of different depths of *Pinus tabuliformis* and *Amorpha fruticose* on soil shear strength

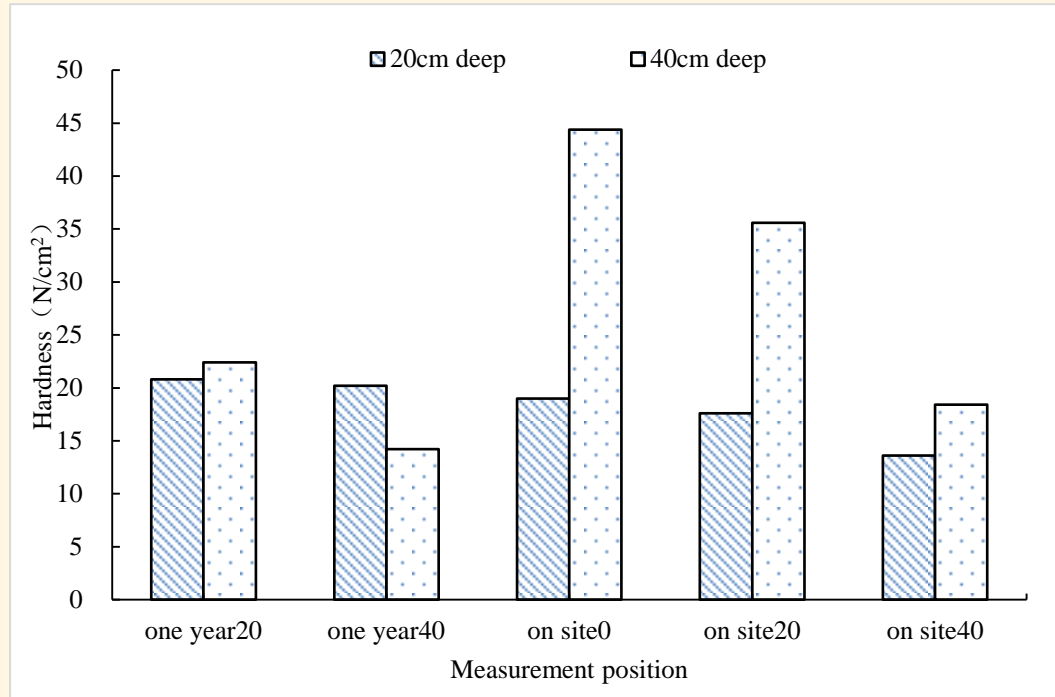

The effect of transplanting one-year-old *Pinus tabuliformis* on soil shear strength decreased with increasing soil depth; the effect of field transplanting *Pinus tabuliformis* on soil shear strength increased with increasing soil depth.

The effect of transplanted one-year-old *Amorpha fruticose* on soil shear strength decreased with increasing soil depth near the root system and increased with increasing soil depth away from the root system; in situ transplanted *Amorpha fruticose* increased with increasing soil depth.

## 4. Influence of different depths of *Pinus tabuliformis* and *Amorpha fruticose* on soil hardness

The effect of transplanted one-year *Pinus tabuliformis* on soil hardness increased with increasing soil depth near the root system and decreased with increasing soil depth away from the root system; field transplanted *Pinus tabuliformis* increased with increasing soil depth.

The effect of transplanted one-year-old *Amorpha fruticose* on soil hardness increased with increasing soil depth near the root system and decreased with increasing soil depth away from the root system; in situ transplanted *Amorpha fruticose* increased with increasing soil depth.

## 5. Differences in the effects of different vegetation on soil shear strength and hardness

- The shear strength and hardness of the measured points at 0 cm from the plant root near system were significantly higher than the other locations.

**Analysis:** As this area is close to the plant root system, the roots and soil are tightly bound together when measured at this location, and the shear strength is significantly increased by the entanglement of plant roots when measured with the cross-plate shear gauge. The root type of *Pinus tabuliformis* is a vertical root type with well-developed horizontal roots, while the root type of *Amorpha fruticosa* is a vertical root type with well-developed horizontal roots.

**Pinus  
Tabuliformis**

**20cm from the root system in the plane**

**Amorpha  
fruticosa**

**0cm from the root system in the plane**

The following conclusions were drawn from studies on the resistance of soil to slope stabilisation in different vegetation and at different soil depths.

- ◆ Within the influence of vegetation root system, the influence of tree and shrub roots on soil consolidation capacity increases with the increase of soil depth; and the influence on soil consolidation capacity decreases with the increase of distance from the root system at the same level.
- ◆ The difference in root type made a difference in their ability to fix the soil, with tree roots having a stronger effect on soil fixation than shrub roots under the conditions of this test.

A sunset scene over a body of water. The sun is low on the horizon, creating a bright orange and yellow glow in the sky and a reflection on the water. The water is calm with gentle ripples. In the distance, there is a dark silhouette of a shoreline with trees and some structures. On the left side of the image, there is a vertical blue bar with a yellow wavy line separating it from the rest of the image.
