# Introduction – Study area

- InSAR data → Displacement time series per evaluated pixel → identify areas of high displacements

**To quantify the times at which the displacement rate of the slow moving landslide changes.**

We developed a **new method**

Evaluated method in two study areas:

- Mud Creek landslide in California, United States
- Mazar region, South-east Ecuador (Figure 1)

**Figure 1.** InSAR velocity in south-east Ecuador including the major city of Cuenca and the Mazar hydropower complex.

# Method

Applied to all pixels  
in the study area

### Outlier Detection

- Remove outliers from displacement time series of selected pixels

- Fit linear models to displacement time series
- Find breakpoints (i.e., time at which there are accelerations or decelerations)

### Model fitting, evaluation and selection

Applied to all pixels  
with successfully  
modelled time series

### Spatial analysis

- Pixels in a cluster that show breakpoints at the same time.
- Quantify selected pixels' number of accelerations or decelerations

**Inventory of  
accelerations  
and  
decelerations**

Applied to the time series  
of each selected pixel

Pixel selection

Outliers

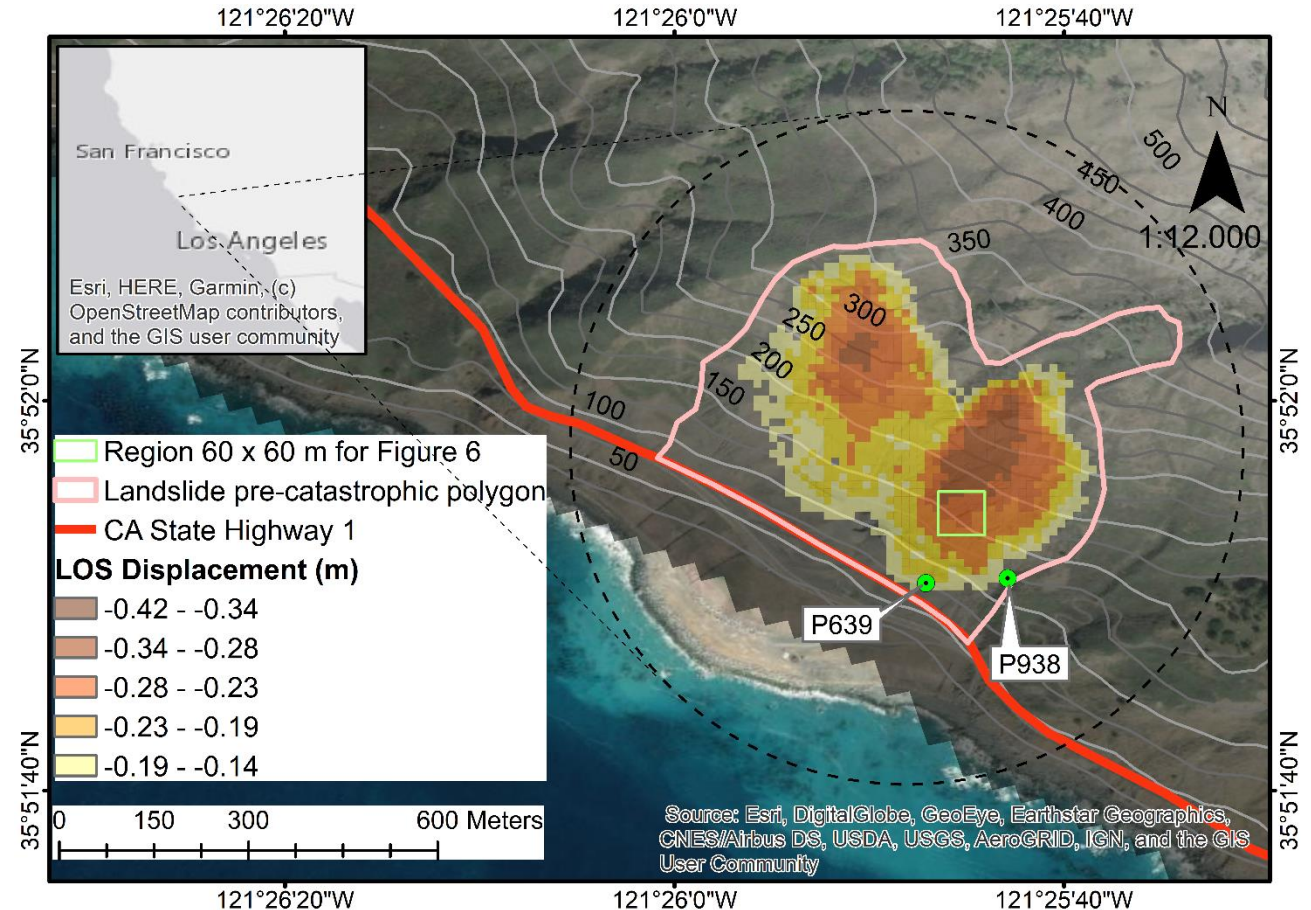

Fitting

Spatial analysis

- In the Mud Creek landslide, 1124 pixels with an absolute displacement value above the 98th percentile were selected.
- All selected pixels are within the boundaries of the pre-catastrophic polygon defined in other studies.

Pixel selection

Outliers

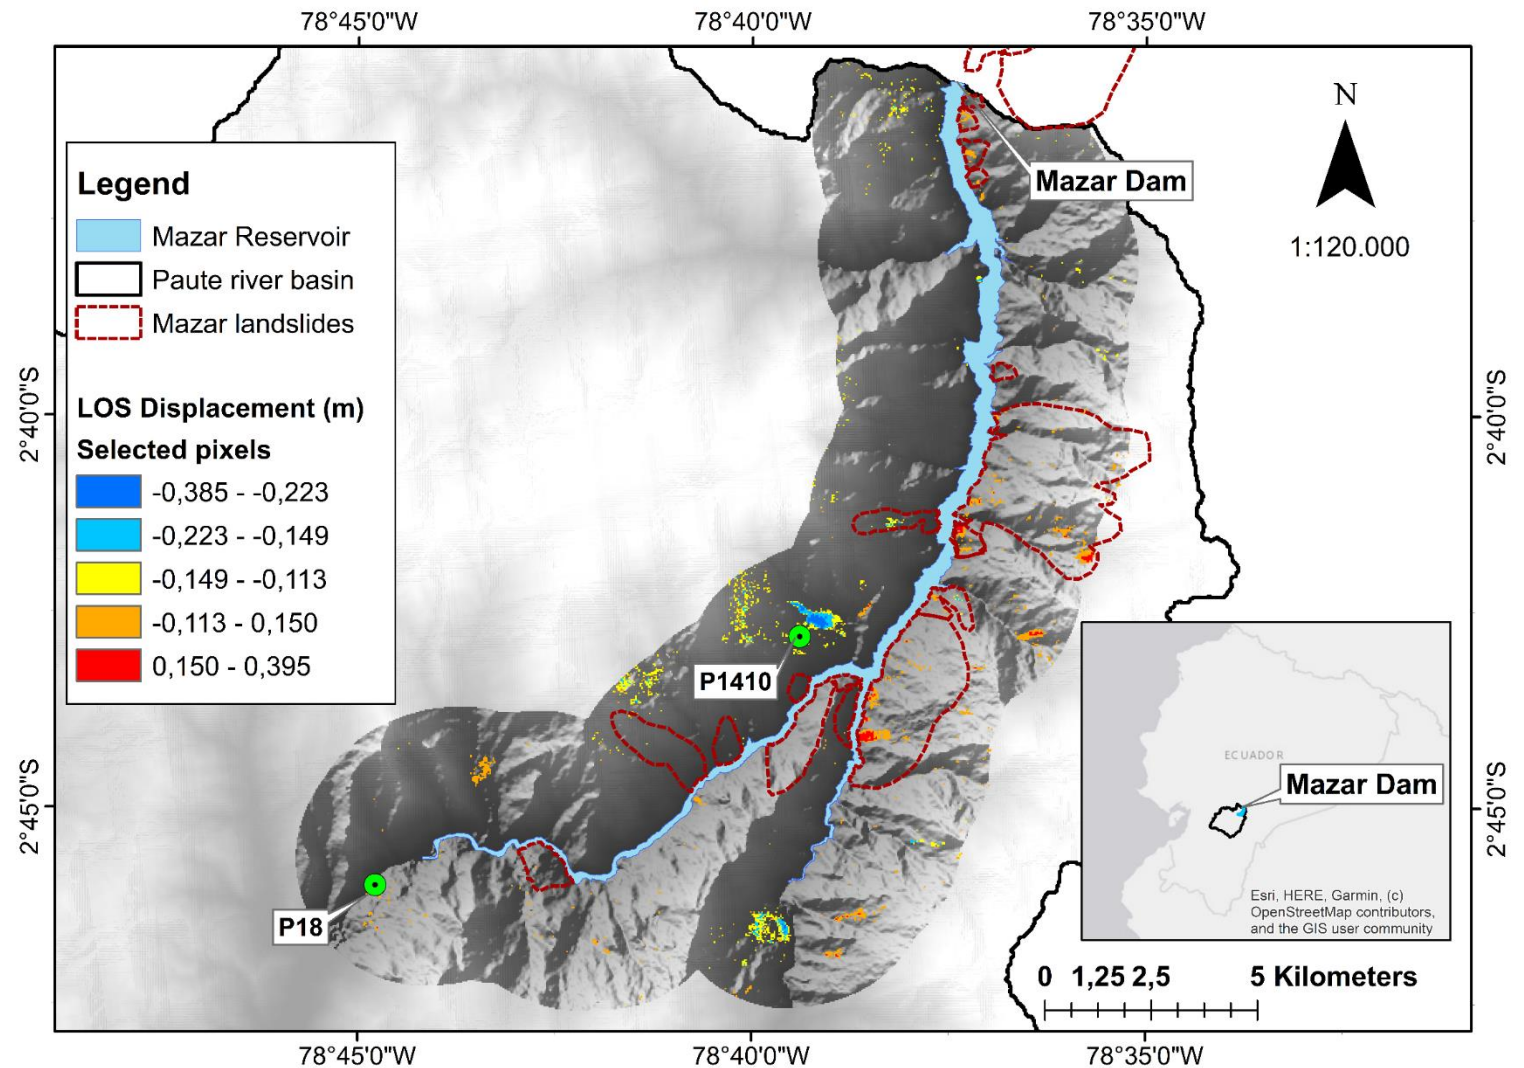

Fitting

Spatial analysis

- In the area of interest in Ecuador, 3230 pixels with an absolute displacement value above the 98th percentile were selected within an area of 211 km<sup>2</sup> around the reservoir.

Pixel selection

Outliers

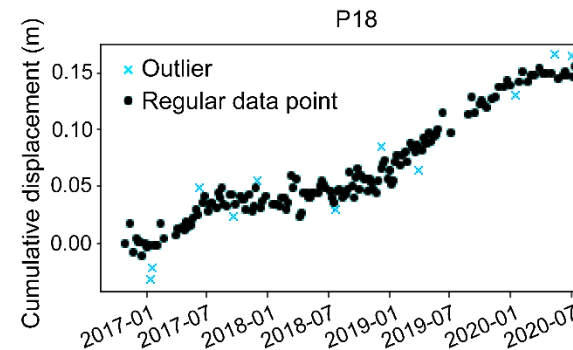

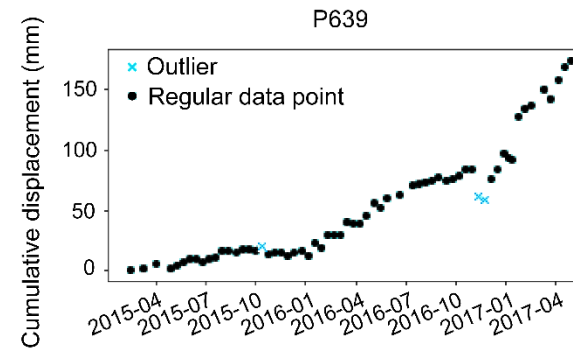

Fitting

Spatial analysis

- Very few outliers were detected and removed from this high quality data set in Mud Creek
- In the case of the Mazar area more outliers were found.

< AIC 2BP  
< AIC 4BP

Pixel selection

Outliers

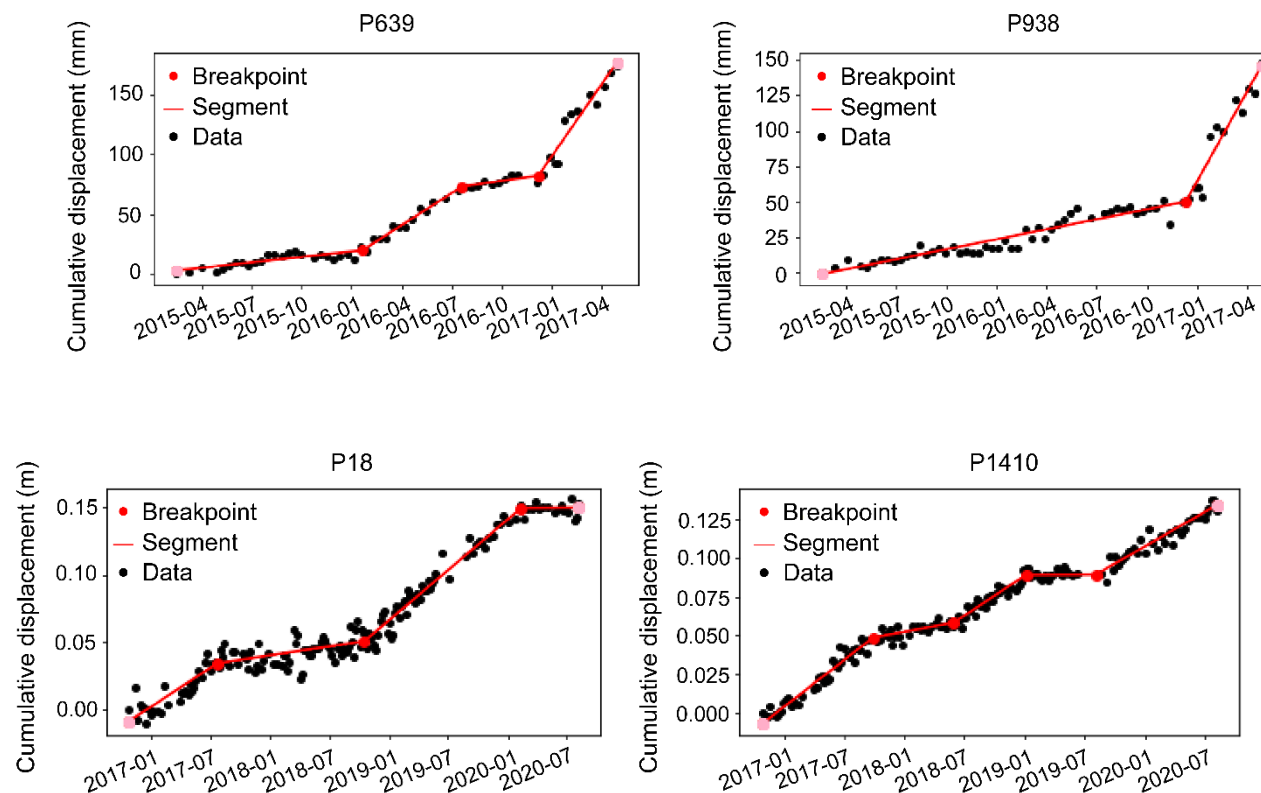

Fitting

Spatial analysis

- Defined number of breakpoints per time series
- Important → the timing of accelerations and/or decelerations is associated with an uncertainty.

Pixel selection

Outliers

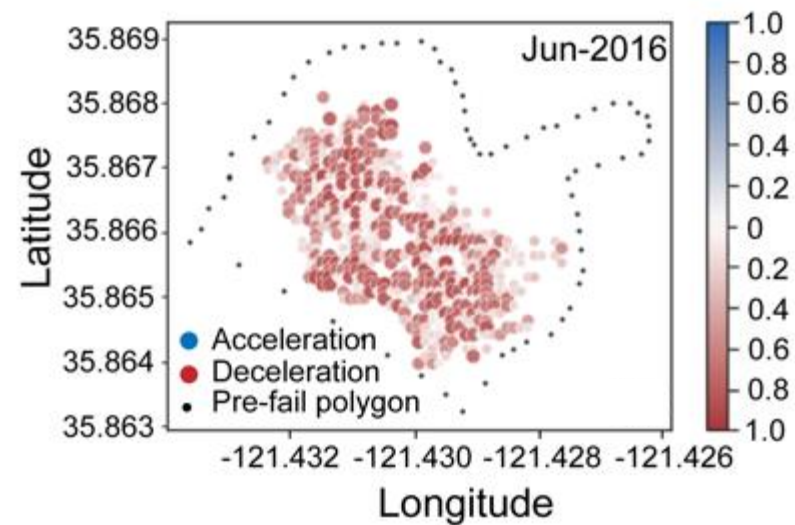

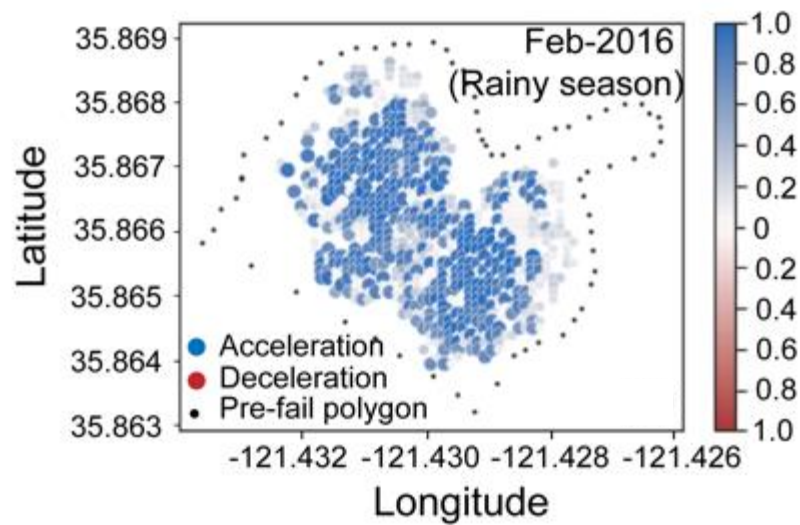

Fitting

Spatial analysis

- We use the **DBSCAN algorithm** to select pixels that are in a cluster and have a change in velocity in the same month

Pixel selection

Outliers

Fitting

Spatial analysis

- We quantify the number of accelerations and decelerations in the entire landslide area per month.

Pixel selection

Outliers

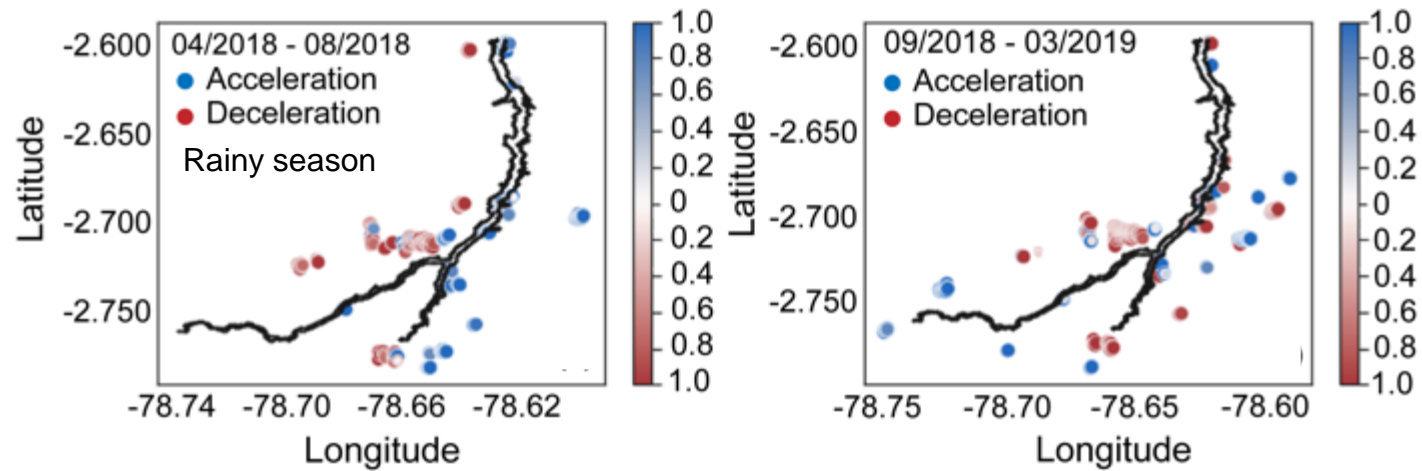

Fitting

Spatial analysis

- We use the **DBSCAN algorithm** to select pixels that are in a cluster and have a change in velocity in the same season

Pixel selection

Outliers

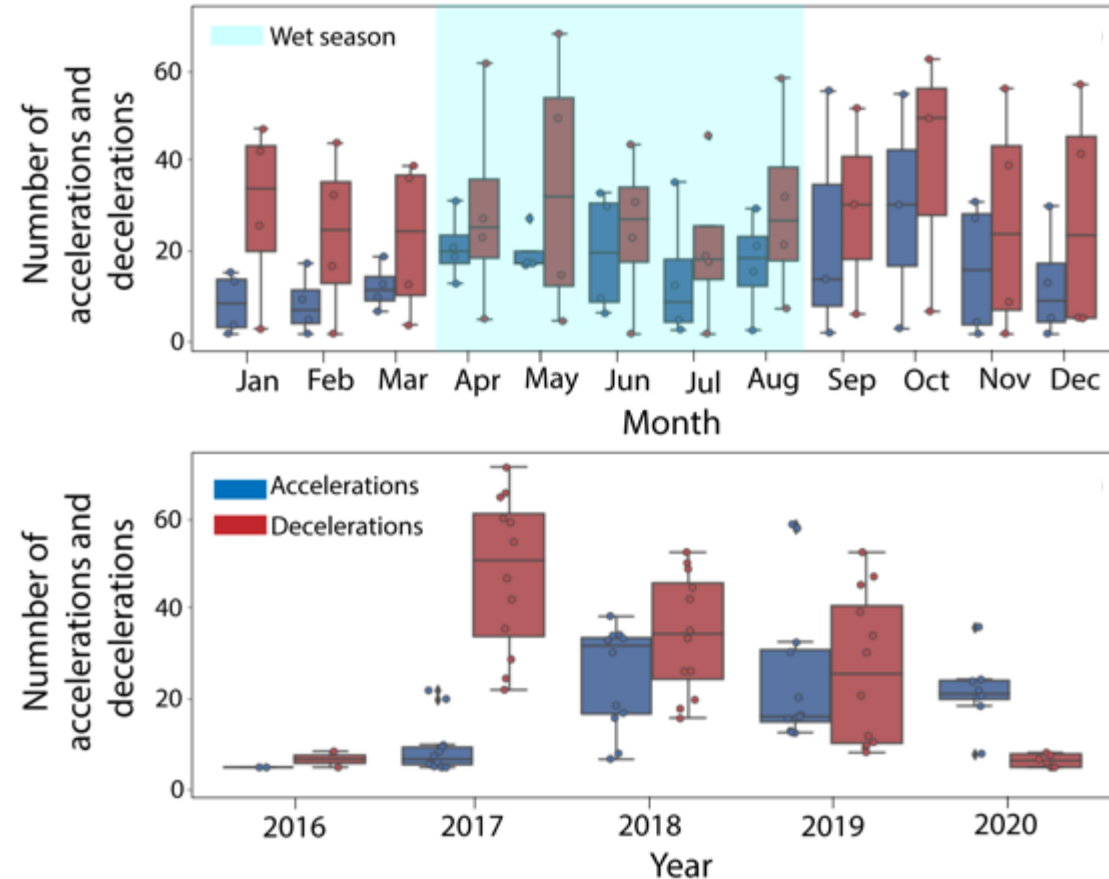

Fitting

Spatial analysis

- We quantify the number of accelerations and decelerations in the region.
- We observe accelerations and decelerations occurring throughout the year, with a higher number of accelerations in the first months of the year.
- The number of decelerations diminishes by the end of the period, with more accelerations in 2020 than decelerations.

# Concluding remarks

- We developed an objective and systematic method for the detection and quantification of accelerations and decelerations of slowly deforming areas from InSAR data.
- The ability to determine the temporal and spatial variation of velocity changes is a step forward in the large-scale interpretation of the physical behavior of slow-moving deforming areas at both sub-landslide and regional scales with high spatial and temporal resolution.

Thank you for your attention
