FME = **F**raction of **m**aximum potential **e**nrichment

$$\text{FME} = \frac{^{18}\text{O EAF DNA}}{^{18}\text{O EAF soil water}}$$

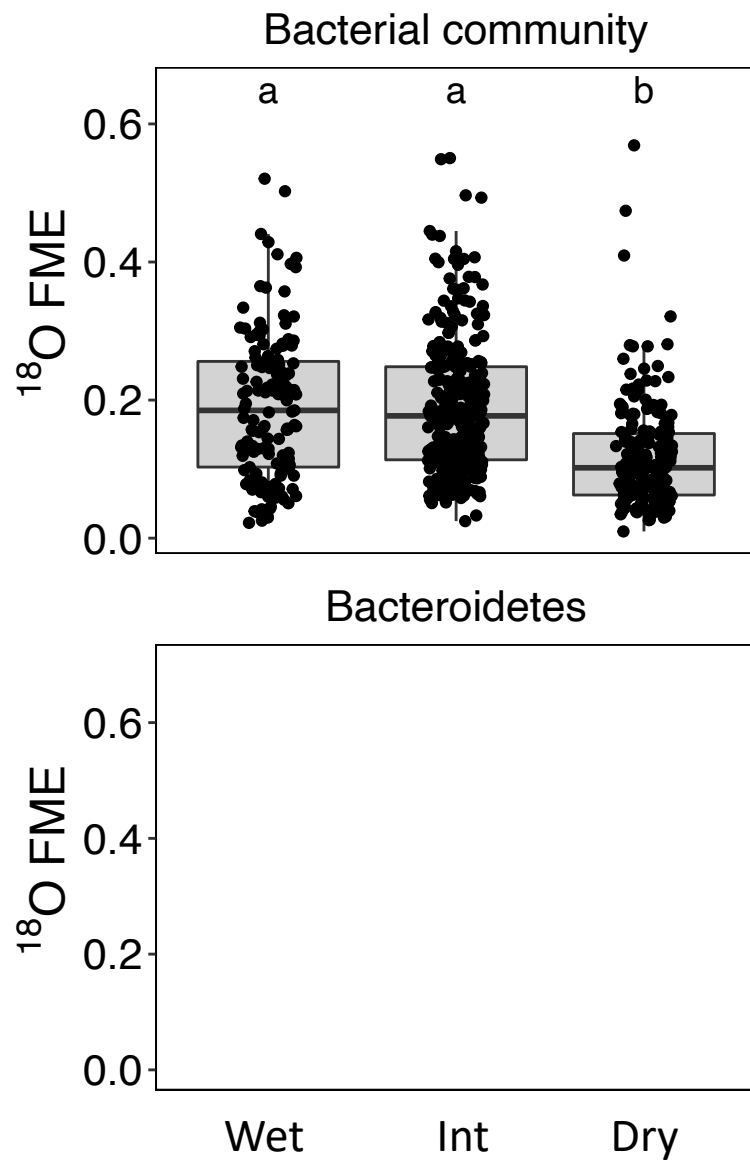

# Growth will be slowest at the driest site, reflecting a long-term legacy effect of climate

FME = Fraction of maximum potential enrichment

$$\text{FME} = \frac{^{18}\text{O EAF DNA}}{^{18}\text{O EAF soil water}}$$

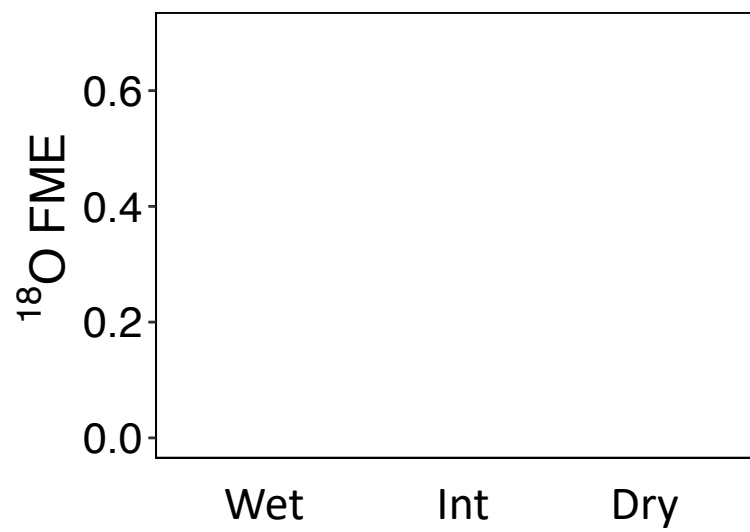

Acidobacteria

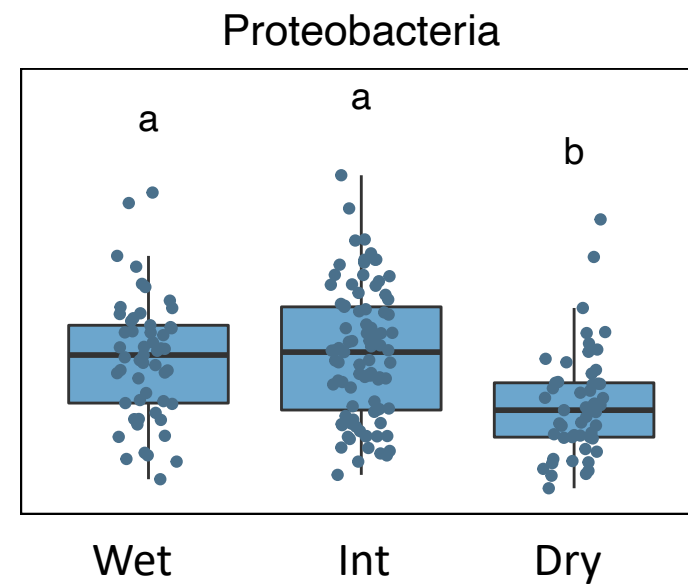

Actinobacteria

Bacteroidetes

Gemmatimonadetes

Proteobacteria

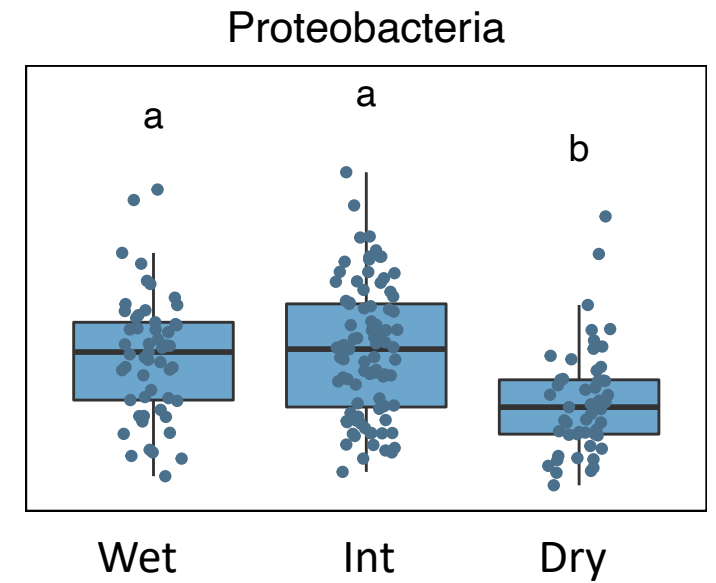

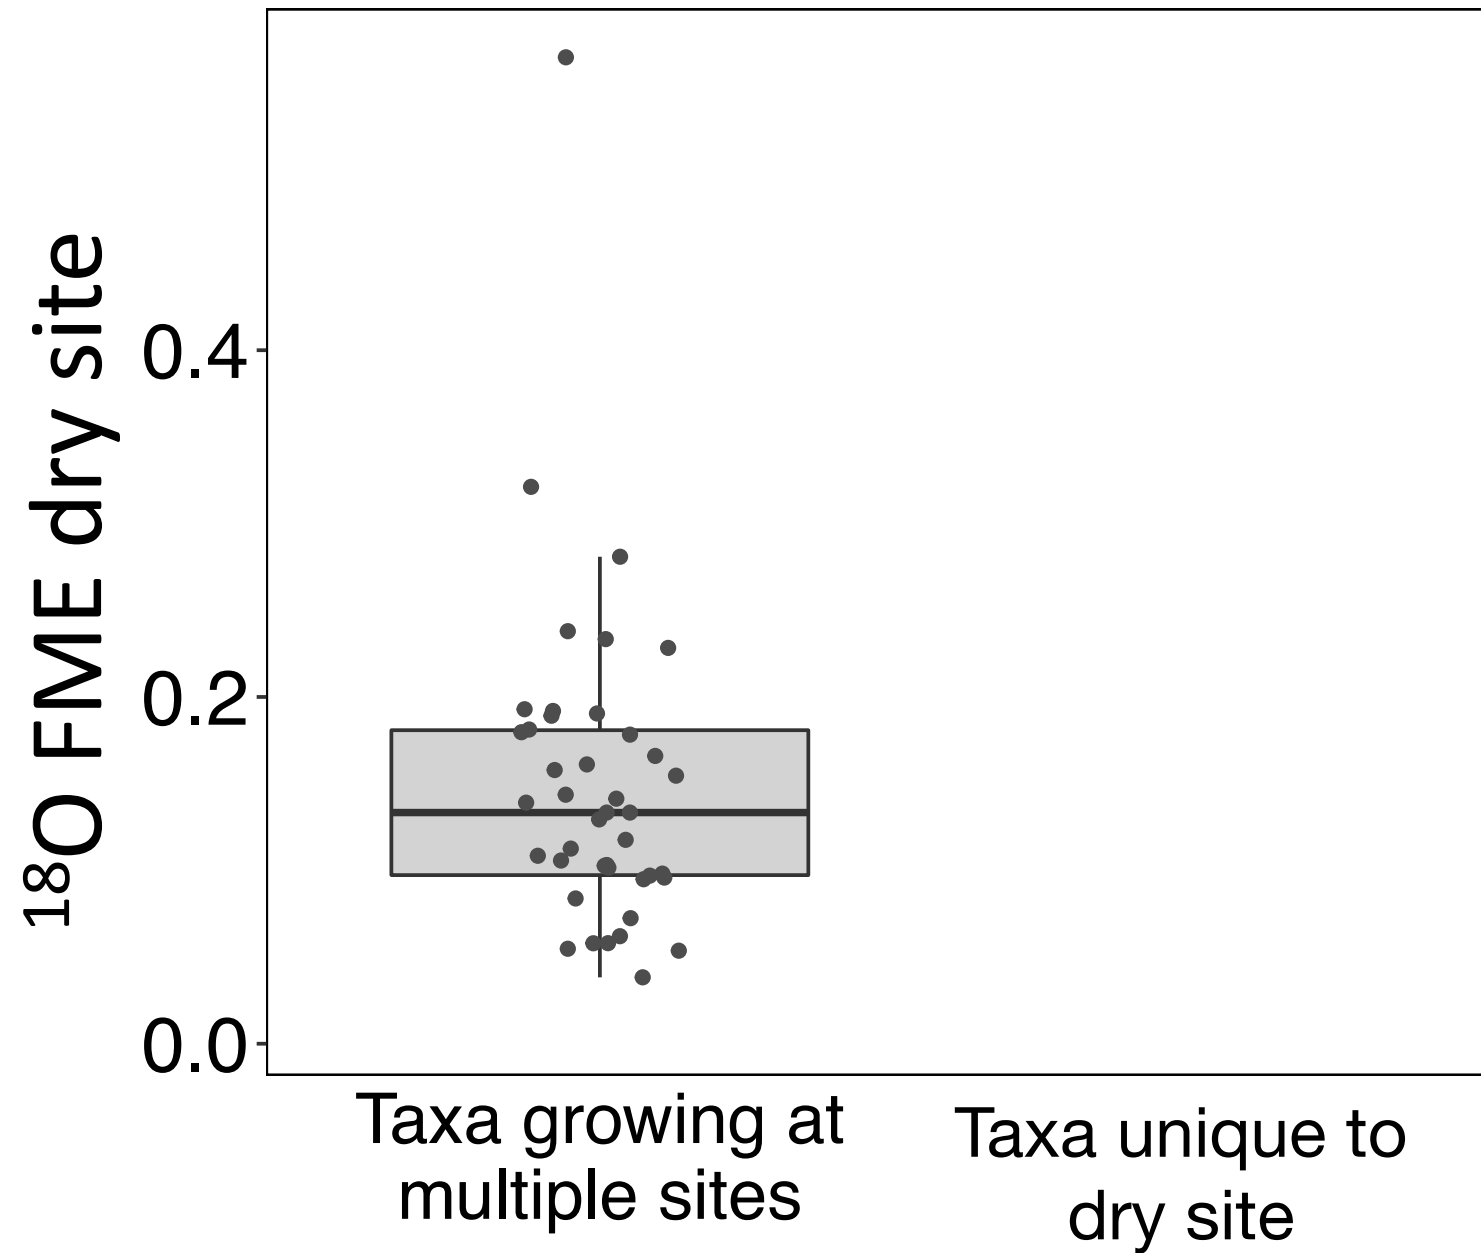

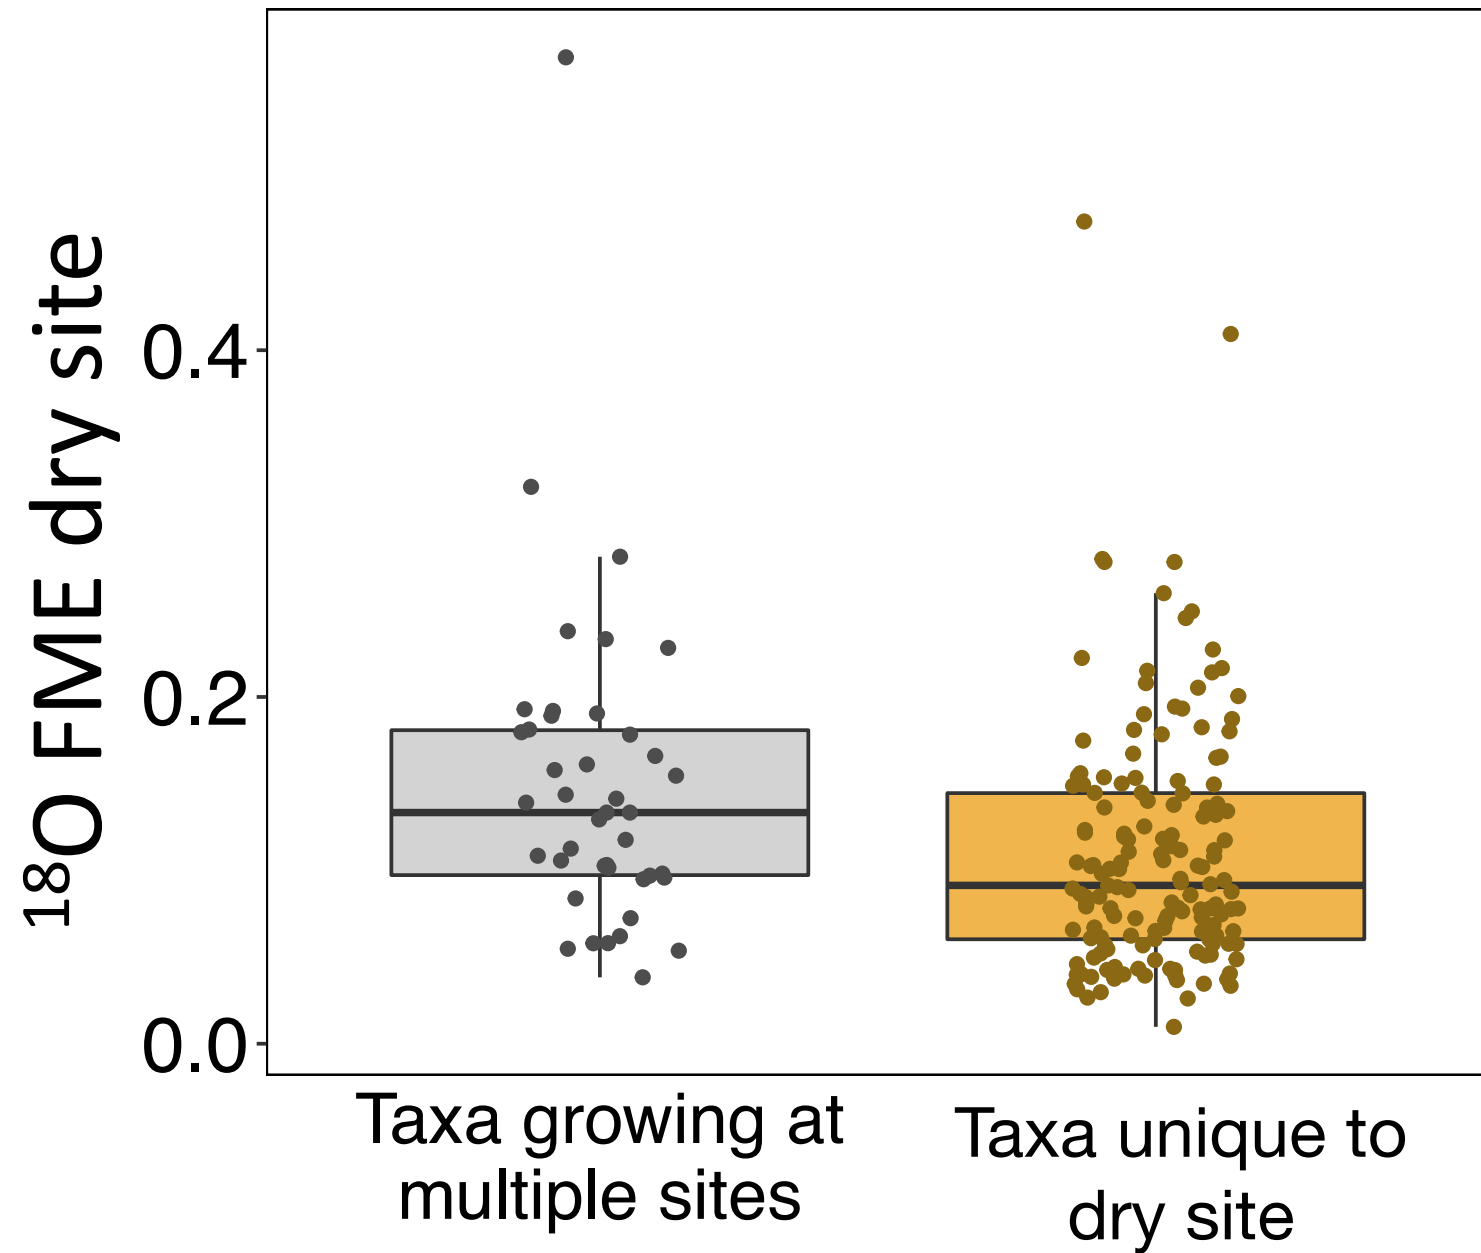

# Growth is slowest at the driest site, even when water is not limiting

# Conclusions

**Growing community structure**

**Climate history frames microbial growth**

# Conclusions

## Growing community structure

→ On a regional scale growing communities are no more similar than total communities, suggesting a strong influence of climate

→

## Climate history frames microbial growth

→

→

# Conclusions

## Growing community structure

- On a regional scale growing communities are no more similar than total communities, suggesting a strong influence of climate
- Despite favorable conditions for growth, only 28% - 58% taxa were growing

## Climate history frames microbial growth

# Conclusions

## Growing community structure

- On a regional scale growing communities are no more similar than total communities, suggesting a strong influence of climate
- Despite favorable conditions for growth, only 28% - 58% taxa were growing

## Climate history frames microbial growth

- Growth was slowest at the driest site, even when water was not limiting
- Growth capacity is reduced by repeated exposure to low soil moisture through environmental filtering for slow growing taxa
