

# Role of storage reserves in new tissue growth quantified using bomb $^{14}\text{C}$ at the alpine treeline

**Boaz Hilman**, Emily Solly, Frank Hagedorn, Iris Kuhlman, David Herrera-Ramírez, and Susan Trumbore

**ETH** zürich

# The bomb-radiocarbon clock

Data from Levin et al. (2010), Tellus B and  
Levin et al. Personal communication (recently submitted to Tellus)

$\Delta^{14}\text{CO}_2$

**Aboveground tissues**  
*up to several years old*

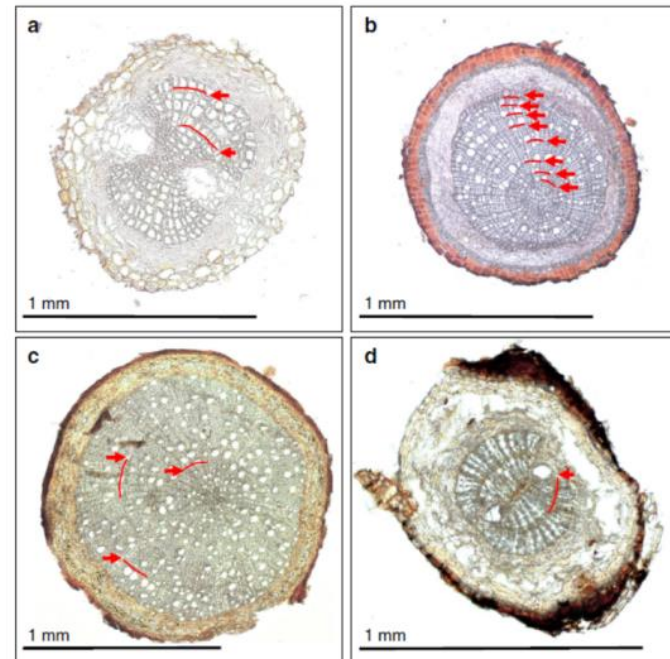

**Fine roots  $\leq 2$  mm**  
*Up to 20 years old*

# $^{14}\text{C}$ age $\neq$ Longevity

- $^{14}\text{C}$  age  $>$  chronological age determined by annual ring count
- Substrate with old  $^{14}\text{C}$  age can support new growth

What controls the variability in the  $^{14}\text{C}$  age of the substrate?

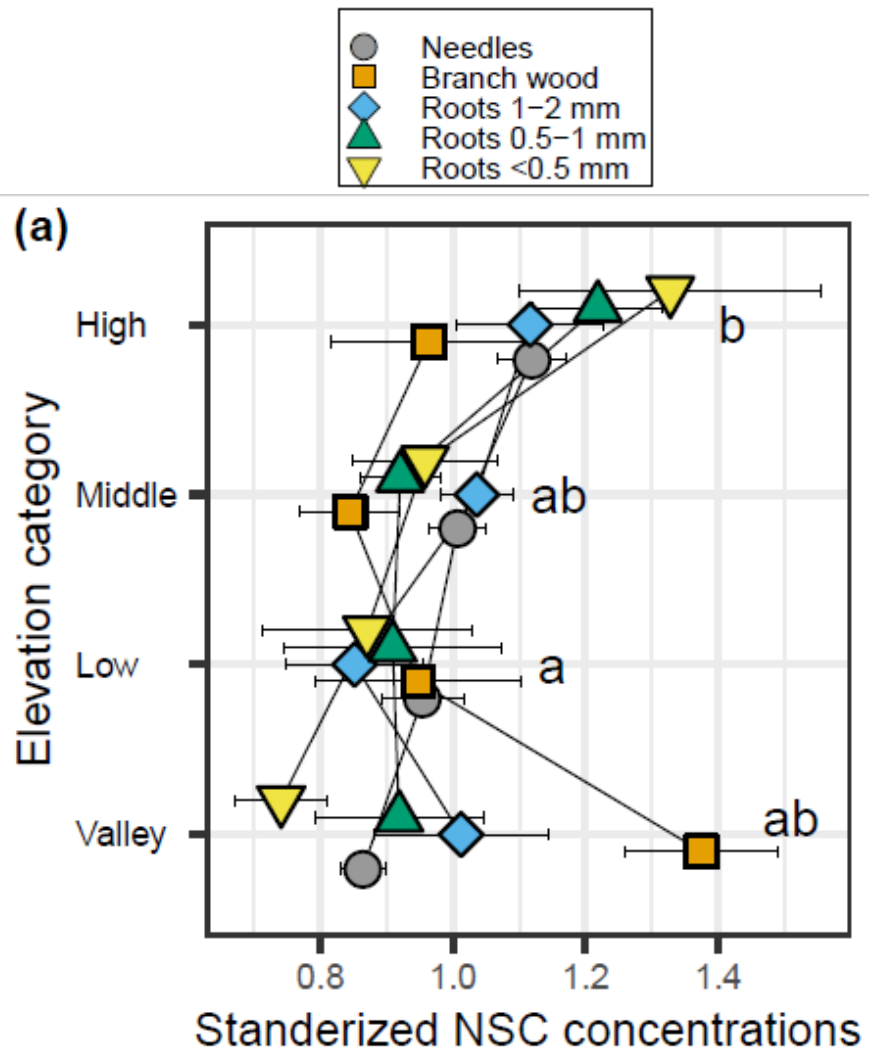

Solly et al. 2018

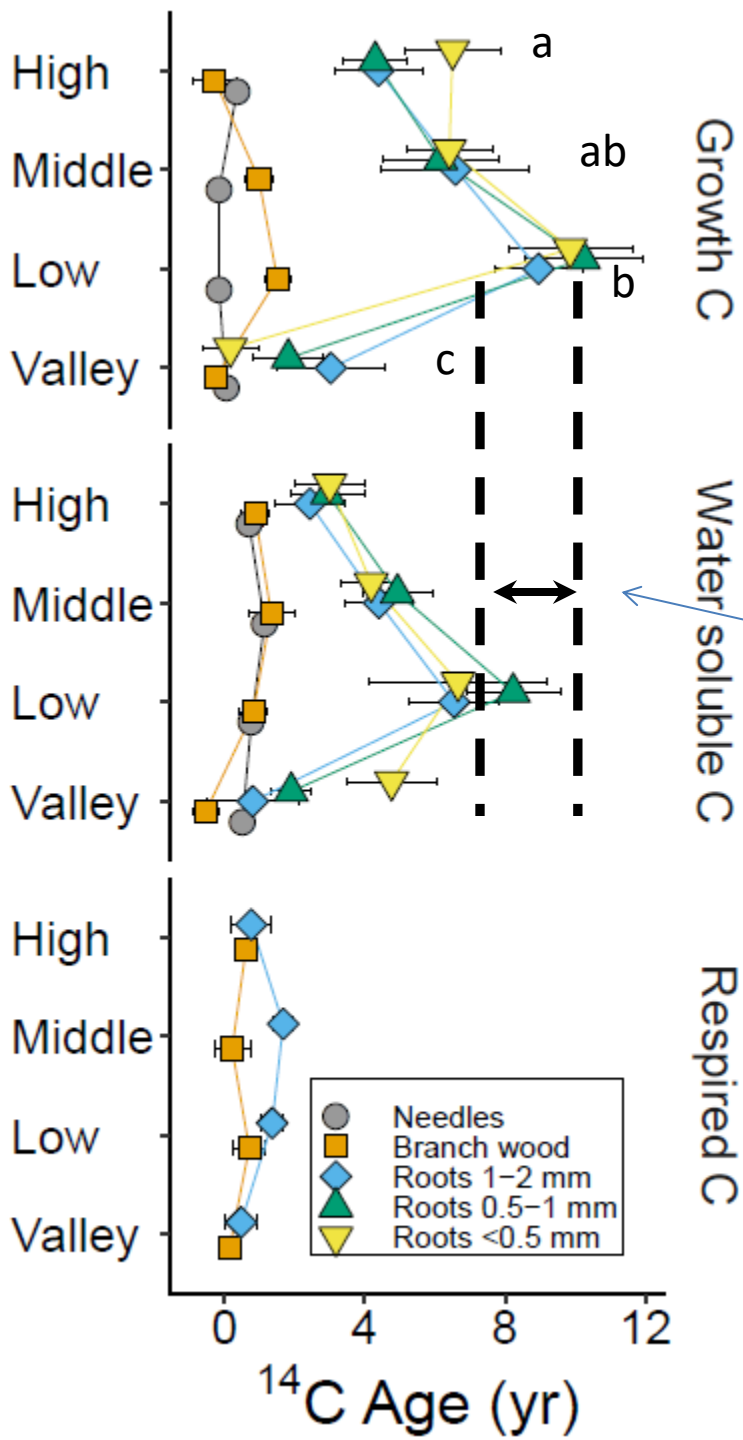

## High altitude treeline ecotone

Larger mobile pool → slower NSC turnover rate → older  $^{14}\text{C}$  age

Growth C = cellulose  $^{14}\text{C}$  age – chronological age

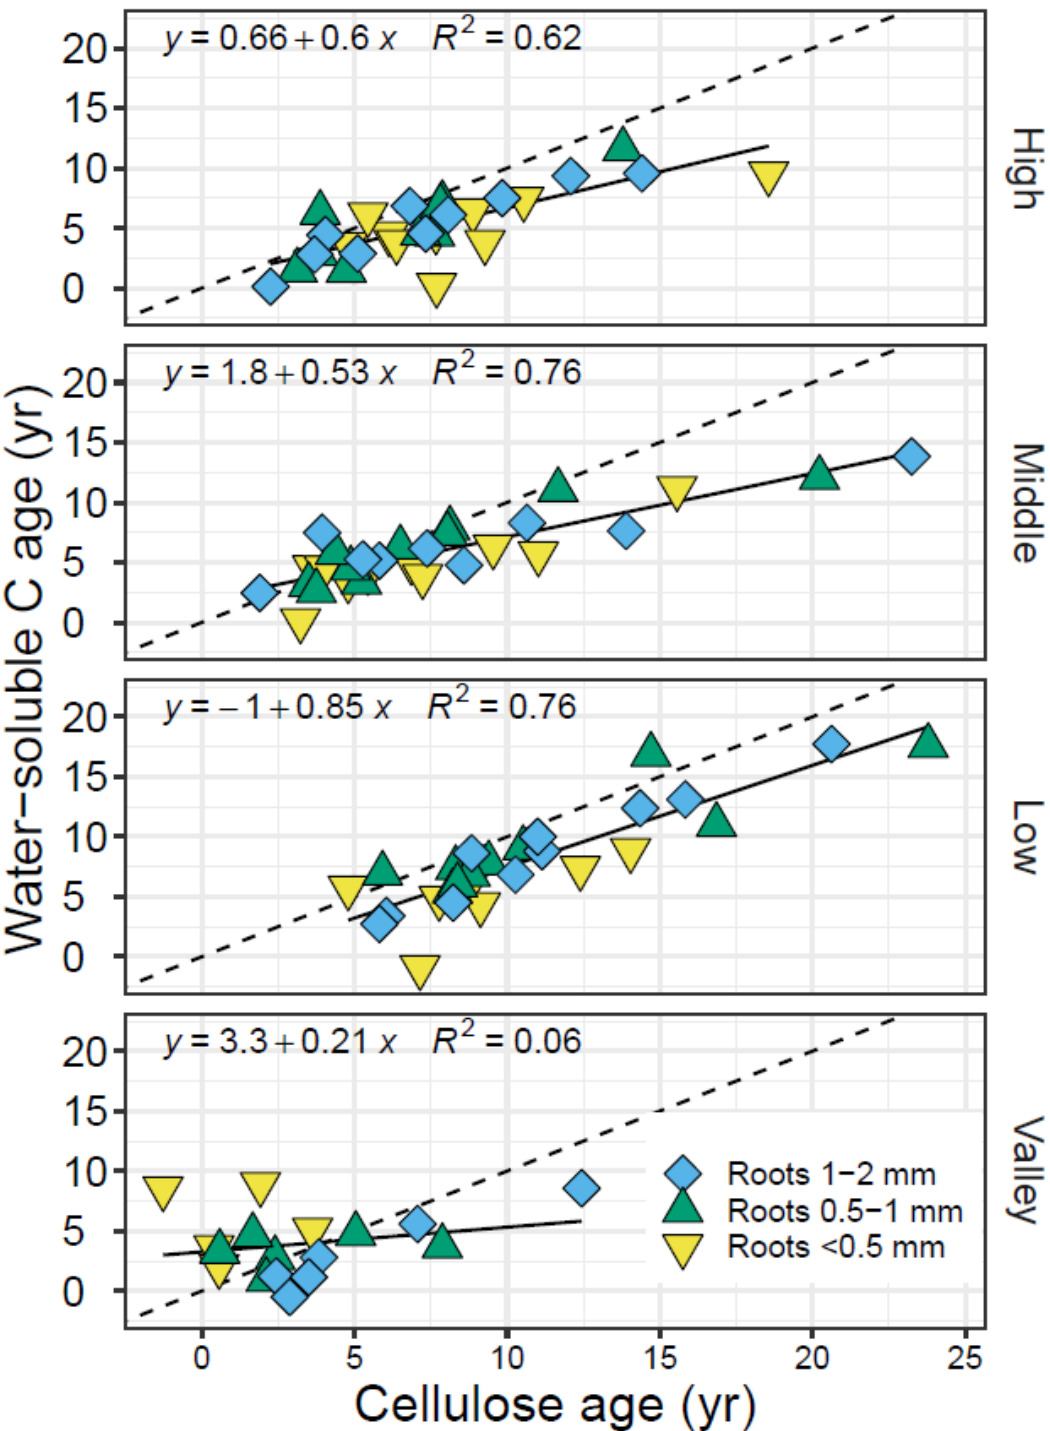

Kirk, 1985

Solly, 2018

Mixing in of young C

Transport

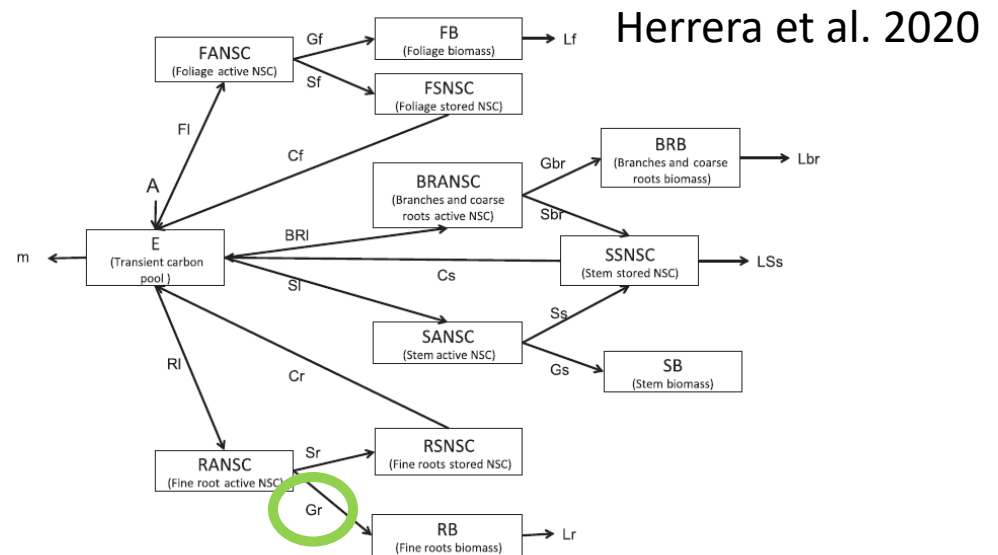

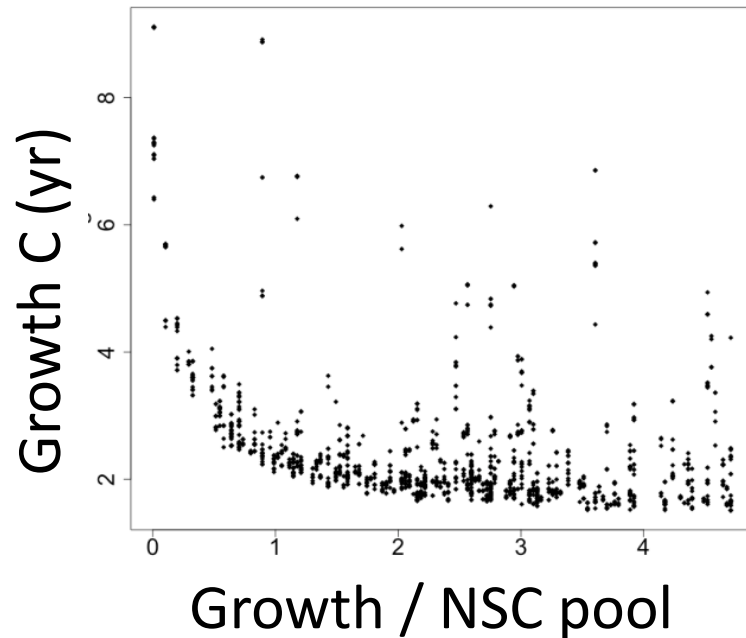

Water-soluble C

Group	Active fraction (GLMM)
All roots	40%
<0.5 mm	74%
Low	14%

# Carbon allocation model

- Less C is allocated to roots (lower growth) – slower turnover time – older roots

Previous studies found fine roots mass reduction with warming

# Conclusions

## Surplus Carbon

Growth      Roots 1.5 yr

Active
