## Multidisciplinary approach

1

Semi-structured  
questionnaire

Field survey

2

Hydrogeological  
investigations

Socio-hydrogeological  
approach

3

Overview of the  
pollutions

Identification of  
pollution sources

4

## Key findings

- Coastal hydrosystems are usually **groundwater dependent**. They provide good and services from which human societies take advantage. However they are very fragile and vulnerable environments submitted to various anthropogenic pressures. **Groundwaters**, due to their invisible nature, are still **poorly understood**, damaging their management and associated water bodies.
- The use of **classical hydrogeological tools** (physico-chemical parameters, major ions, trace elements, stable isotopes of the water molecule  $\delta^{18}\text{O}$  /  $\delta^2\text{H}$ ) combined with complementary tracers like **emerging organic compounds** (EOCs) and **pesticides** are useful to understand the hydrogeological functioning of those hydrosystems.
- Also the **socio-hydrogeological approach**, including social and economic components into hydrogeological investigations, helps to understand the relations between population and groundwater. It allows to identify more precisely the pollution sources and dispersion modalities of pollutant fluxes towards groundwater dependent ecosystems.

OSPP Contest

**Socio-hydrogeology** : indicator of the relations between the population and groundwater.  
Including socio-economic dimension in the classical hydrogeological investigations.

## Methodology:

- Development of a **semi-structured questionnaire** around **4** axes :
  - Past and present water uses
  - Land uses evolution since 1950
  - Population's perception on groundwater and the lagoon
  - Perception on anthropogenic impacts
- **25** water users interviewed and **16** local stakeholders
- **Field campaign** combining sampling and field survey led in **spring 2021**
- Hydrogeological investigations including **chemical**, **geochemical** and **isotopic** analysis ( $^2\text{H}/^{18}\text{O}$ ) carried out on **53** sampling points
- **21** sampling points for **pesticide** analysis
  - **11** molecules found among a **screening** of **240** molecules and metabolites

**Water use**

*Do you own a well or a borehole ?*  
☐ Yes ☐ No

*How often do you use the water from your well / borehole ?*  
☐ Daily  
☐ Seasonal  
☐ Rarely

**Land use evolution in time**

*What type of land use do you have on your field?*

*With what type of molecules do you usually treat your crops or garden?*  
☐ Natural molecules  
☐ Phytosanitary molecules  
☐ No molecules

**Population's knowledge about water resources and Biguglia lagoon**

*According to you, what is the main fresh water resource on the watershed?*  
☐ Surface water  
☐ Precipitation  
☐ Groundwater

*What does the Biguglia lagoon represent for you?*  
☐ Environmental interest site  
☐ Unhealthy and polluted site  
☐ Economic interest site

**Human activities**

*According to you, which water bodies are the most affected by degradations?*  
☐ Surface water  
☐ Groundwater  
☐ Lagoon  
☐ None

### 2. Socio-hydrogeological approach

### 3. Overview of the pollutions

### 4. Identification of pollution sources

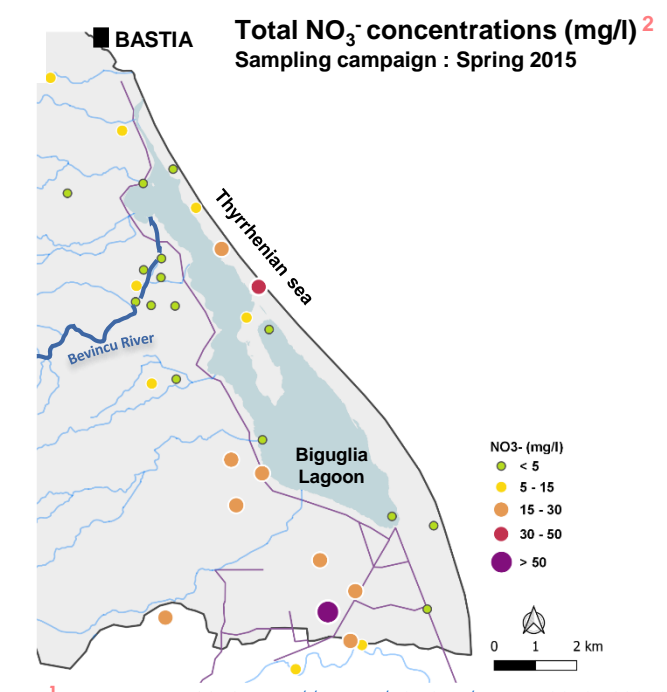

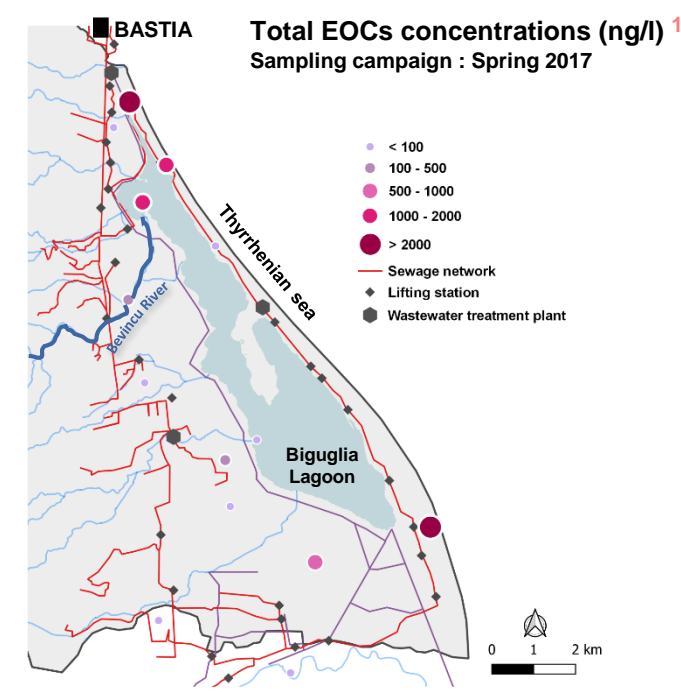

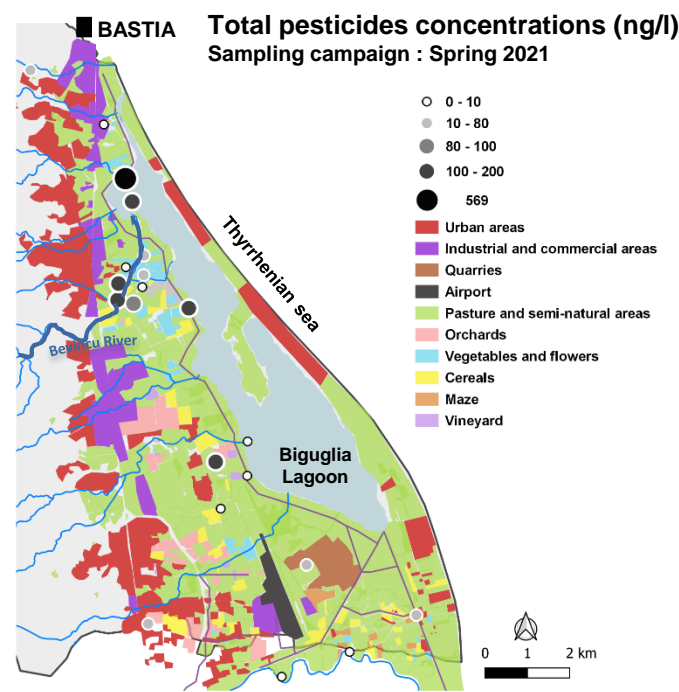

# Overview of the different pollutions identified on the Biguglia Lagoon watershed

## Complementary tracers used for the understanding of the hydrogeological functioning

- **Pesticides** : analysis show a double pollution **agricultural and domestic** (molecules from sanitation defects)  
Also molecules **banned since 20 years** (Fenuron, Simazine)
- **EOCs** : Consumed by the population → **anthropogenic origin** mainly from **untreated sewage waters**
- **NO<sub>3</sub><sup>-</sup>** : Contamination with a double origin : **nitrogen from the soil & sewage waters**

## Various anthropogenic pollution sources from past and present uses

### 3. Overview of the pollutions

### 4. Identification of pollution sources

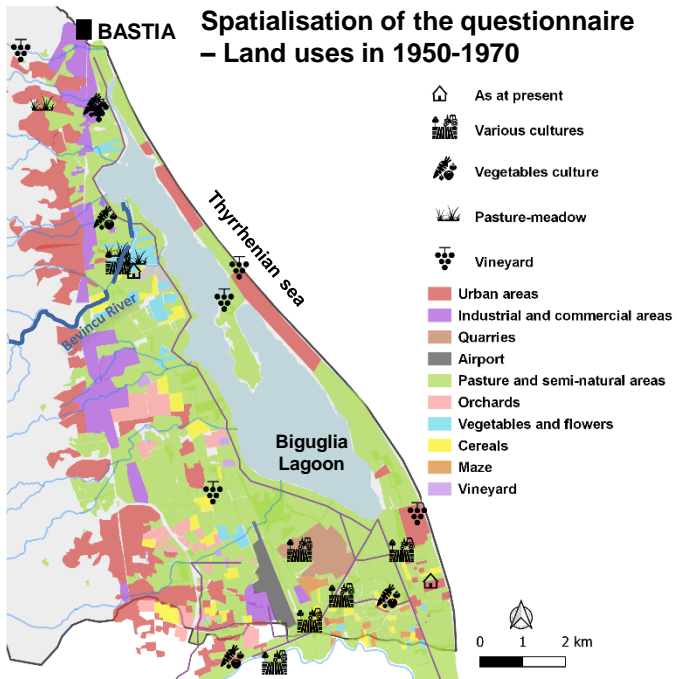

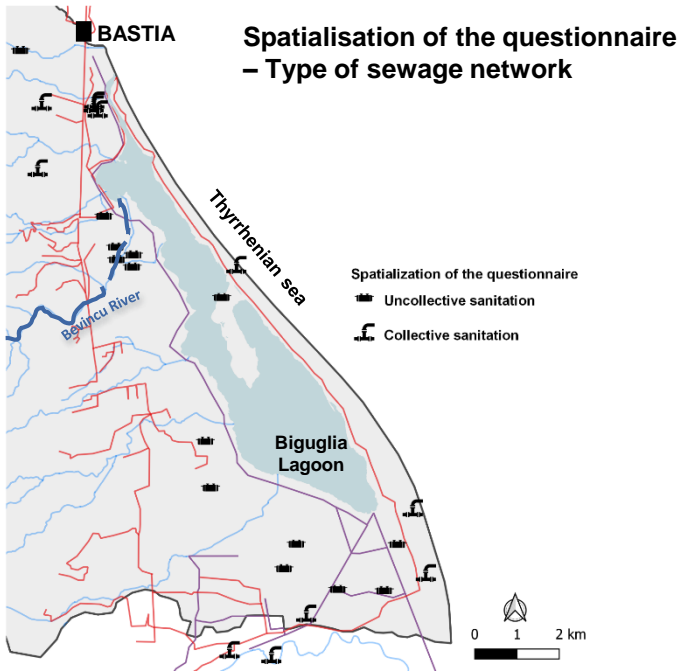

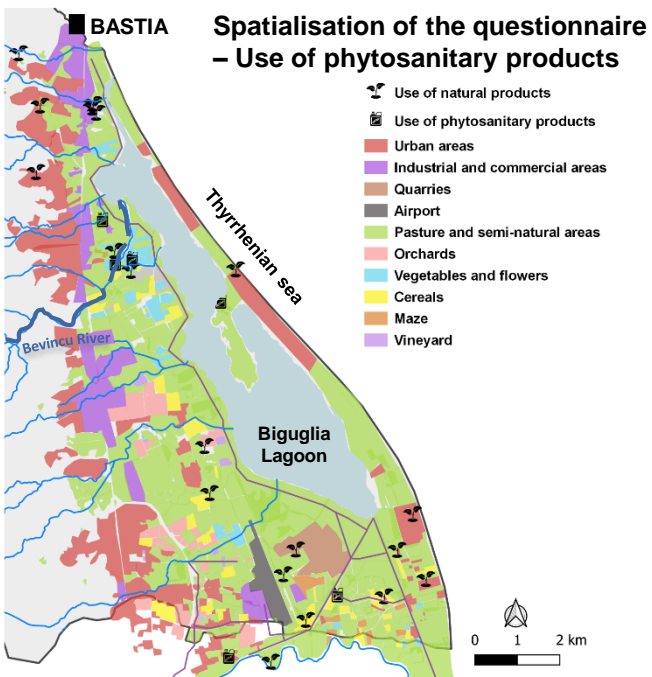

# Identification of precise pollution sources

The combination of **hydrogeological investigations** with the **questionnaire** and the **field survey** allows to identify :

- Agricultural pollution as **very local** : at the **plot scale**  
➔ Pesticides identified correspond to **agricultural practices on the plain** identified during the field survey and by the questionnaire
- The sewage network **completed** with the questionnaire highlight that the pollution with **EOCs and NO<sub>3</sub><sup>-</sup>** in « recent waters » come from **sanitation defects and septic tanks**
- Land uses in 1950-1970 confirm the **pollution legacy** and the **storage capacity** of groundwater

## 1. Study site

## 2. Socio-hydrogeological approach

## 3. Overview of the pollutions

## 4. Identification of pollution sources

- **Hydrogeological investigations** combined with the **socio-hydrogeological approach** have allowed to identify precise pollution sources in relation to the **water use** and **land use evolution** in time on the watershed
- These specific pollutants are considered as **relevant tracers** of the coastal **Mediterranean anthropization phenomenon**
- The **storage capacity** of groundwater is, most of the time, **underestimated** and not always **taken into account** by resource managers and ecologists
- This new knowledge will help **local stakeholders** to take into account scientific investigations in order to **protect groundwater resources and associated waterbodies**
