

# Future climate and runoff projections in Naltar Catchment, Upper Indus Basin from CORDEX-South Asia models and hydrological modelling

Muhammad Usman Liaquat<sup>1</sup>, Ana Casanueva<sup>2</sup>, Giovanna Grossi<sup>1</sup> and **Roberto Ranzi<sup>1</sup>**

<sup>1</sup>Department of Civil, Environmental, Architectural Engineering and Mathematics, Università degli Studi di Brescia-DICATAM, Via Branze, 42, 25123 Brescia, Italy.

<sup>2</sup>Meteorology Group, Department of Applied Mathematics and Computer Sciences, University of Cantabria, 39005 Santander, Spain

**EGU General Assembly 2022 Vienna, Austria, 23–27 May 2022**

# Research Objective

- ✓ Assess if the ‘Karakoram anomaly’ (e.g. Faronotti et al., Nature Geosciences, 2020) i.e. a slower retreat of glaciers in the Karakoram region can be confirmed for the Naltar catchment, in the southern side of the Karakoram (Upper Indus Basin)
- ✓ To examine the overall performance of Physical Based Distributed Snow Land and Ice Model PDSLIM model to compute snow and ice melt contribution to runoff regime and floods.
- ✓ Project changes of the hydrological regime under Climate changes scenarios

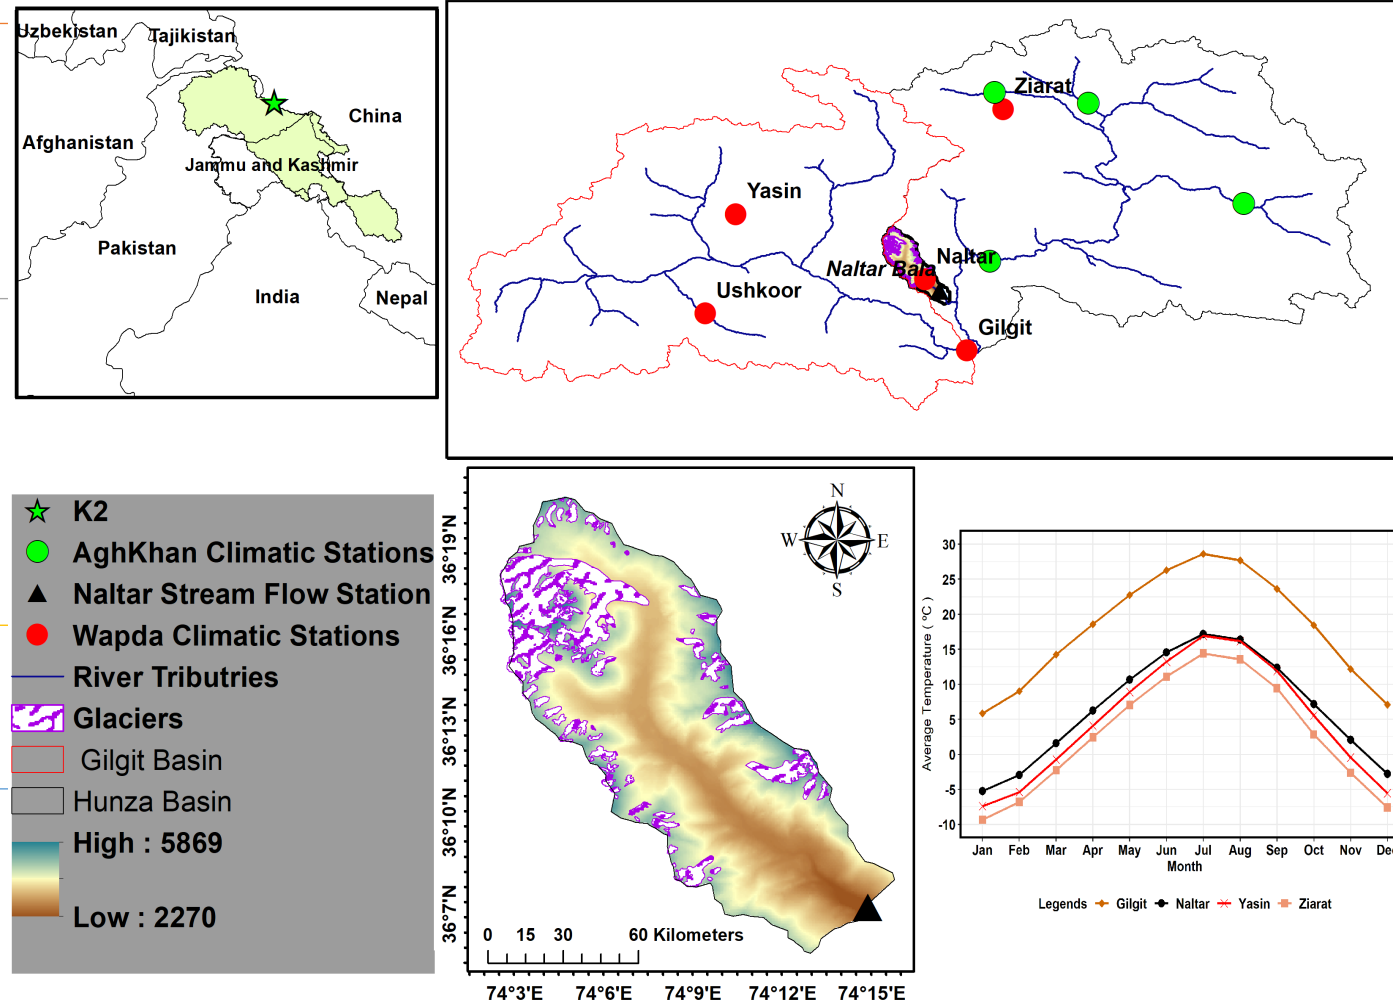

# Naltar Catchment

The Naltar catchment covers up to **243 km<sup>2</sup>** .  
Around **42.8 km<sup>2</sup>** area is covered with glaciers.  
The largest glacier is Shani glacier (area **19 km<sup>2</sup>**)

It is situated in Hunza basin about 42 km away from Gilgit city and 208 km from **K2 (the second largest mountain range in world)** in the Gilgit-Baltistan region of Pakistan, in the southern side of Karakoram

The elevation of Naltar catchment varies from 2270 m to 5869 m with mean elevation 4064 m.

The average annual precipitation and temperature recorded at Naltar station are **685 mm** and **6.5°C**

Hourly P, T, RH, V, p, R meteorological station and daily runoff in Naltar station close to the outlet

# Seasonal cycle of additive climatological change factor of Temperature

# PDSLIM Model Structure

(PDSM Ranzi & Rosso, 1991 for snow;

Ranzi et al., 2010 + ice; Grossi et al., 2013 + CC projections of glacier)

The PDSLIM model consist of two main cycles: time and spatial cycle:

In **time cycle**, model executed each hour of the day within a spatial cycle that calculates the individual components of the energy balance on each cell of the area of interest considered.

The energy available for glacierized surface is calculated by

$$H_m + H_c = S_{io} + L_{io} + H_l + H_s + H_p + H_g$$

Here unit of all terms are  $W/m^2$

$H_m$ : energy available for melt,

$H_c$ : Internal Energy of the snow or ice layer,

$S_{io}$ : net shortwave radiation,

$L_{io}$ : net longwave radiation,

$H_l$ : latent heat,

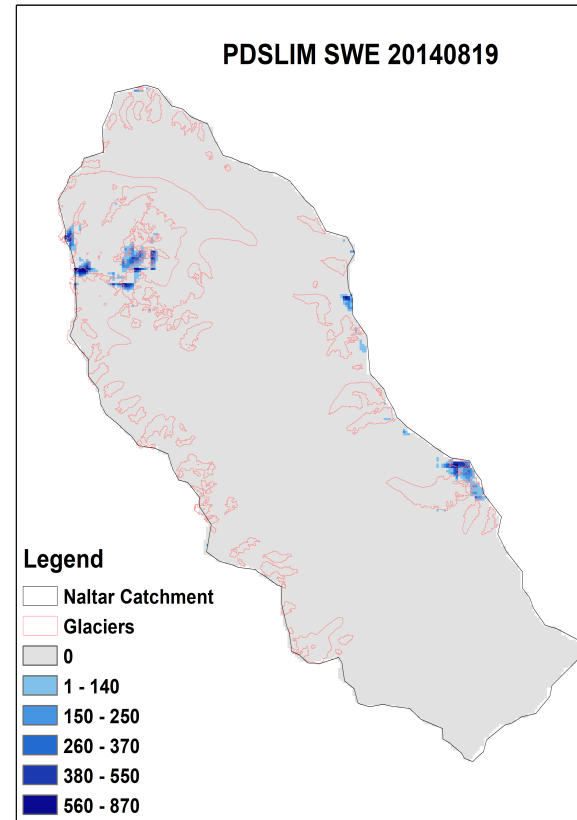

$H_s$ : sensible heat,

$H_p$ : advective heat from precipitation,

$H_g$ : Conductive heat at the bottom side of the snow or ice layer

# Conclusions

- ✓ The results exhibited satisfactory performance of the distributed energy-balance model against satellite-based snow cover area for all simulated years.
- ✓ Runoff simulations revealed good agreement with observed daily discharge obtained with NSE of **0.87 and 0.88** for calibration and validation period.
- ✓ From the actual (-1500 mm) and projected mass balance (-2900 mm by 2050\_4.5; -4200 mm 2050\_8.5) estimates and the MODIS+LANDSAT satellite images it appears that also in the Naltar catchment glaciers are going to retreat fast indicating an exception to the 'Karakoram anomaly'.
