## 10 **Results**

### 11 **1 Interspecific difference in foliar nitrogen concentration, $\delta^{15}\text{N}$ and $\Delta^{15}\text{N}$**

12 Foliar N concentration of Dahurian larch ( $17.0 \pm 2.0 \text{ mg g}^{-1}$ ) was lower than that of  
13 Mongolian oak ( $25.8 \pm 4.0 \text{ mg g}^{-1}$ ) (paired t test,  $t = -11.12$ ,  $P < 0.001$ ; Fig. 2a). Foliar  
14  $\delta^{15}\text{N}$  showed significantly lower values in Mongolian oak ( $-1.3 \text{ ‰} \pm 0.9 \text{ ‰}$ ) than in  
15 Dahurian larch ( $1.2 \text{ ‰} \pm 2.9 \text{ ‰}$ ) ( $t = 4.70$ ,  $P < 0.001$ ; Fig. 2b). Similarly,  $\Delta^{15}\text{N}$  of  
16 Mongolian oak ( $-4.8 \text{ ‰} \pm 1.1 \text{ ‰}$ ) was significantly lower than that of Dahurian larch  
17 ( $2.3 \text{ ‰} \pm 3.0 \text{ ‰}$ ) ( $t = 4.46$ ,  $P < 0.001$ ; Fig. 2c). Besides, there existed weak correlation  
18 between Mongolian oak and Dahurian larch in foliar N ( $P = 0.127$ ; Fig. 2b),  $\delta^{15}\text{N}$  ( $P =$   
19  $0.689$ ; Fig. 2d) and  $\Delta^{15}\text{N}$  ( $P = 0.598$ ; Fig. 2f).

### 20 **2 Effect of Mongolian oak encroachment on nitrogen nutrition of Dahurian larch**

21 Variation of foliar N were mainly explained by basal area percent (BAP), MAT, MAP  
22 and stand aspect (total variance explained 64.2%; Fig. 2a). Conditional regression  
23 model showed that foliar N of Dahurian larch was positively correlated with basal area  
24 proportion of Mongolian oak (variance explained 16.3%,  $P < 0.01$ ; Fig. 2b), but  
25 decreased with MAP (variance explained 18.3%,  $P < 0.01$ ; Fig. 2a), MAT (variance  
26 explained 14.6%,  $P < 0.01$ ; Fig. 2d) and stand aspect (variance explained 15.0%,  $P <$   
27  $0.01$ ; Fig. 2e).

28 Foliar  $\delta^{15}\text{N}$  and  $\Delta^{15}\text{N}$  of Dahurian larch both increased significantly with basal  
29 area proportion of Mongolian oak (variance explained 33.4% for  $\delta^{15}\text{N}$ ,  $P < 0.01$ ;  
30 variance explained 42.3% for  $\Delta^{15}\text{N}$ ,  $P < 0.01$ ; Fig. 5), while the roles of other potential  
31 factors were not statistically important ( $P > 0.05$ ; Fig. 4a & 4f). Specifically, foliar  $\delta^{15}\text{N}$   
32 decreased with herb coverage, stand aspect, and slope (total variance explained 36.7%,  
33  $P < 0.01$ ; Fig. 4c–4e). The variation of foliar  $\Delta^{15}\text{N}$  of Mongolian oak decreased with  
34 stand aspect (variance explained 11.7%,  $P < 0.01$ )

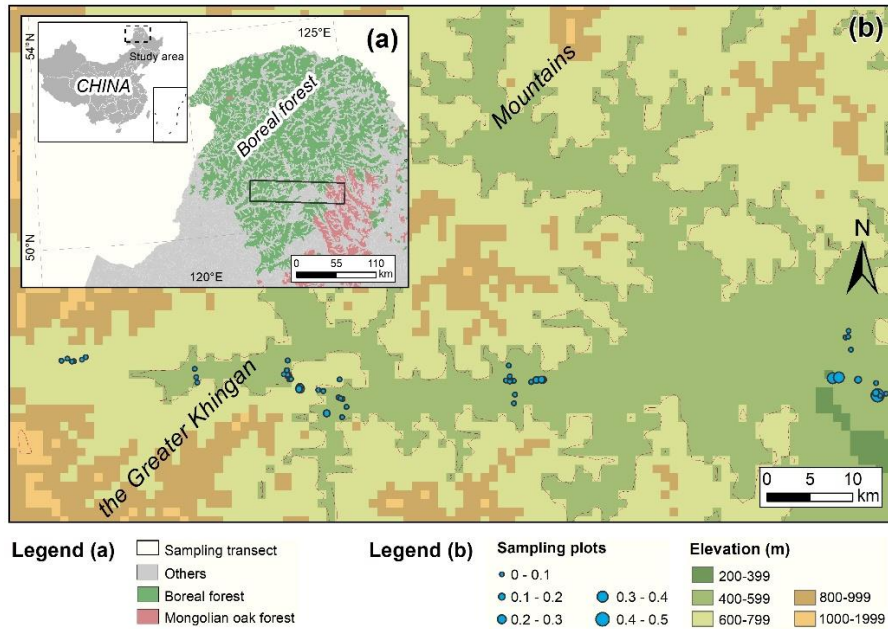

35 Bivariate linear regression model indicated that the basal area increment (BAI) of  
36 Dahurian larch increased significantly with soil  $\delta^{15}\text{N}$  ( $R^2 = 0.15$ ,  $P < 0.05$ ; Fig. 5).

### 37 **3 Effects of Mongolian oak encroachment on soil nitrogen availability**

38 Soil  $\delta^{15}\text{N}$  ranged from 1.62‰ to 5.65‰ across the forest ecotone. The spatial variation  
39 of soil  $^{15}\text{N}$  values was mainly explained by stand slope and aspect (total variance  
40 explained 41.9%) (Fig. 5b). Specifically, conditional regression model showed that soil  
41  $\delta^{15}\text{N}$  decreased significantly with stand slope ( $P < 0.01$ , Fig 5c). Furthermore, soil  $\delta^{15}\text{N}$   
42 varied significantly with stand aspect ( $P < 0.01$ , Fig. 4b). However, basal area

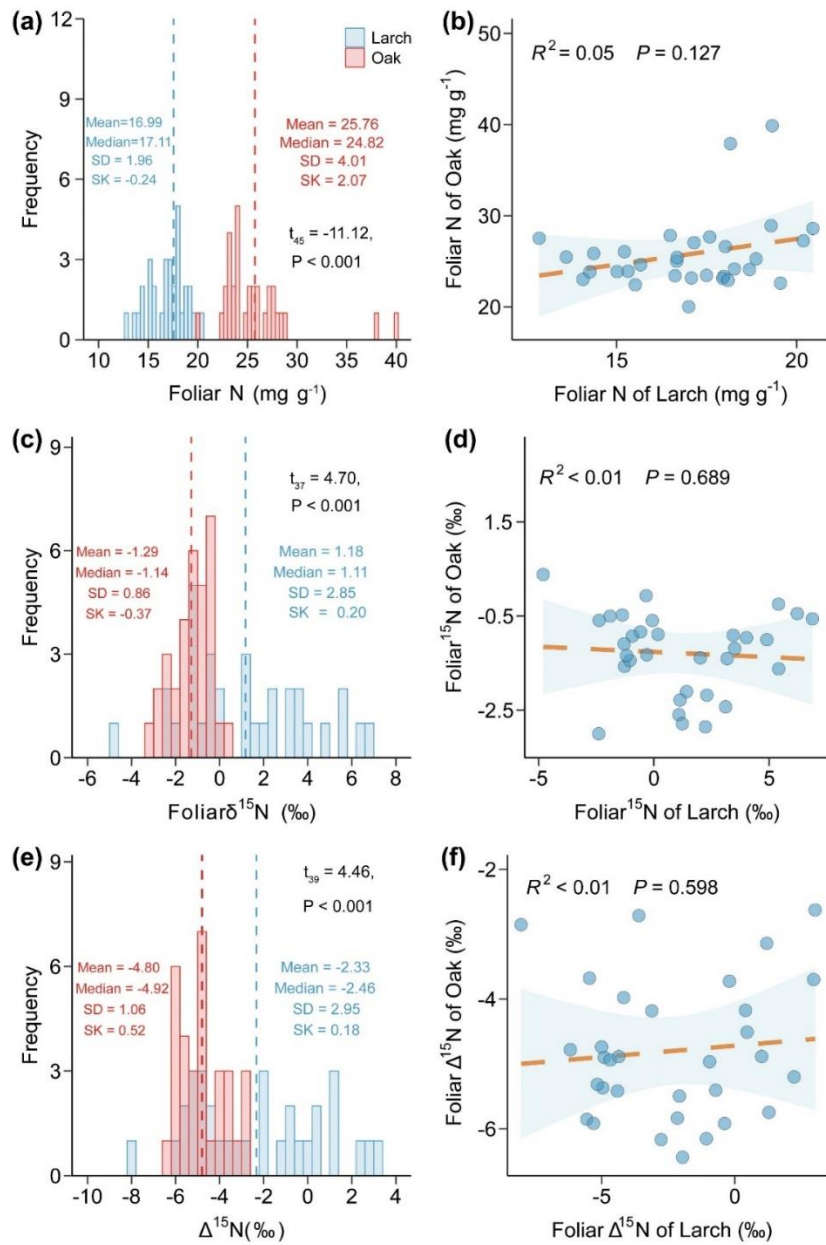

43 proportion of Mongolian oak was not a statistically important predictor of soil  $\delta^{15}\text{N}$  ( $P$   
44 = 0.19; Fig. 4d).  
45

46 **Figure 1. Study area across the temperate-boreal forest ecotone.** Panel (a)  
47 vegetation distribution and sampling transect in the study area; Panel (b) the sampling  
48 plots across the ecotone. Size of blue circle in panel (b) indicates the relative  
49 dominance (e.g., basal area percent, ranging from 0 to 0.5, see Method) of Mongolian  
50 oak in each sampling plot.
