Modelling snow interception in a spruce forest in varying climate

Motivation

Motivation

- Interception is important factor and input value to hydrological models.
- Snow interception is part of the snow storage of the basin
- 20-40% of snowfall is captured by vegetation, and it is known as **interception loss**.
- In general, interception is **very difficult to measure directly**.
- Many models of interception is based on **vegetation structure and interception loss is higher in winter** due to snow precipitation.
- Many mountain basins are mostly covered by vegetation in Czechia

Research goals

- To define vegetation structure by Leaf area index (LAI)
- To adapt the Canadian model of snow interception for the Ptáci Brook basin
- To model snow interception in several winter season in the Ptáci Brook basin, Sumava Mts., Czechia

Hydrologic processes in winter (01/03/2019)

Project No. 354522 is gratefully acknowledged.

OSSP contest

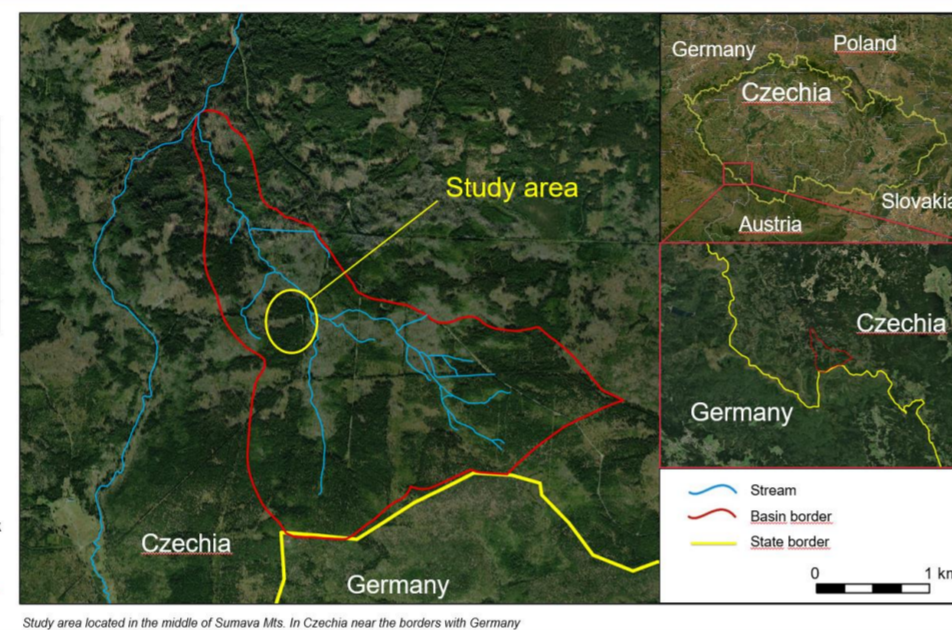

Study area

Study area

Basic characteristics of the Ptáci Brook basin

Stream length	4.3 km
Area	5.5 km ²
Mean network density	2.3 km/km ²
Mean elevation	1130 m a.s.l.
Soil elevation difference	273 m
Mean annual temperature (1960-2015)	4.8 °C
Mean annual precipitation (1960-2015)	1302 mm

- season snowfall
 - about 16% of annual precipitation
- 70% covered by spruce forests
 - severely damaged (43%)
 - by the European spruce bark beetle (lar sporophag)
 - meteorological disturbances

Contact to authors: Charles University, Department of Physical Geography and Geocology, Albertov 6, Prague 2, 128 43 Czech Republic. dominik.mika@natur.cuni.cz, michal.jenicek@natur.cuni.cz

Project No. 354522 is gratefully acknowledged.

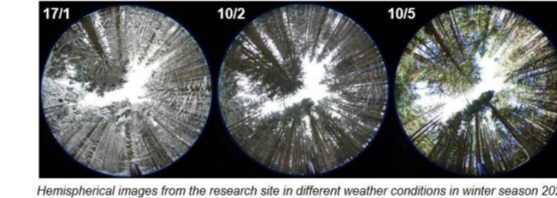

OSSP contest

Methodology

Methodology

Field measurements

- Winter season 2020/21
- Hemispherical images
- Different meteorological conditions
- 15 sites under the canopy

Calibrating hemispherical images with a Pictor K-3 digital mirror camera with Rolayer lens

Canadian model of snow interception
by Hedstrom, Pomeroy (1996)

$$I = c(S_{in} - I_0) \left[1 - \exp\left(-\frac{C_c P}{S_{in}}\right) \right]$$

c – coefficient of snow unload from the canopy (dimensionless)
 I_0 – initial intercepted snow load [mm]
 C_c – canopy closure (dimensionless)
 P – snowfall [mm]
 S_{in} – maximum canopy snow load – $S_{in} = S_{in}(LAI)(0.27 + 46(\rho_s))$
 S_{in} – maximum snow load of branch [spruce – 5.9 mm]
 LAI – Leaf area index
 ρ_s – density of snow [kg m⁻³]

Density of snow

- Equation used in Canadian model (Pomeroy, Gray 1995; Roth, Nolin 2011)
- $\rho_s = 67.92 + 51.25 \cdot e^{\left(\frac{LAI}{100}\right)}$
- Adapted eq. on local conditions (Penaz 2022)
- $\rho_s = 0.2102 + e^{(LAI - 0.1813)}$

Simplified model of snow interception

$$I = P_c - P_f$$

P_c – total snowfall on open area [mm]
 P_f – total snowfall under the canopy [mm]

Direct snowfall measurement is difficult → using snow depth instead is better
 positive snow depth changes as SWE (Snow water equivalent)

Input data

Input data

Characteristics of the winter seasons 2016-2022

Main seasonal meteorological characteristics

Season	monthly SWE of snowfall [mm]	Average air temperature [°C]	Average monthly snow depth [mm]
2016	70.7	-0.27	310.0
2017	62.0	-2.24	354.5
2018	72.1	-1.86	815.5
2019	70.6	-1.34	612.3
2020	53.9	-0.28	243.6
2021	49.2	-0.37	288.7
2022	70.2	-0.40	420.4

Input values of the canopy structure

Percentile	LAI	C _c	S _{in}
10%	2.03	83.54%	5.5 mm
Average	2.84	86.16%	9.2 mm
90%	2.72	80.25%	12.9 mm

Values of LAI are results of field research

Contact to authors: Charles University, Department of Physical Geography and Geocology, Albertov 6, Prague 2, 128 43 Czech Republic. dominik.mika@natur.cuni.cz, michal.jenicek@natur.cuni.cz

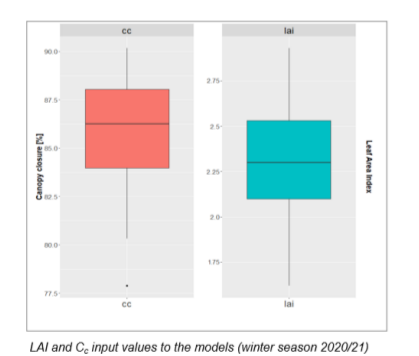

Project No. 354522 is gratefully acknowledged.

OSSP contest

Results - analyzing

Results

Vegetation structure

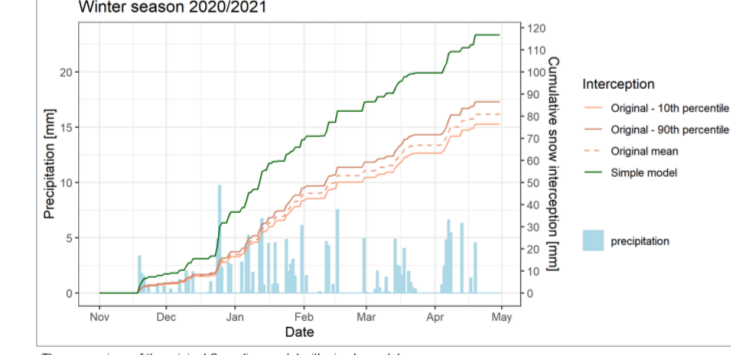

LAI and C_c input values to the models (winter season 2020/21)

Results of LAI were affected by meteorological conditions (clouds vs. sunshine) and by snow interception itself

Snow interception during the winter season

Winter season 2020/2021

The comparison of the original Canadian model with simple model

- Variability of the results depends on input values of the canopy structure
- 43.3-49% was interception loss in winter 2020/21 – little higher than expected

Contact to authors: Charles University, Department of Physical Geography and Geocology, Albertov 6, Prague 2, 128 43 Czech Republic. dominik.mika@natur.cuni.cz, michal.jenicek@natur.cuni.cz

Project No. 354522 is gratefully acknowledged.

Preliminary results

Preliminary results

These results are not final. But correlation between snow interception and meteorological characteristics appeared

Seasonal correlation of snow interception on two main meteorological elements – monthly total snowfall and monthly average temperature

Linear correlation between monthly sum of snow interception and monthly average temperature of all months during winter seasons 2016-2022

$R^2 = 0.8333$
 $y = 0.211x + 3.0231$

$R^2 = 0.3674$
 $y = -2.0639x + 14.582$

Contact to authors: Charles University, Department of Physical Geography and Geocology, Albertov 6, Prague 2, 128 43 Czech Republic. dominik.mika@natur.cuni.cz, michal.jenicek@natur.cuni.cz

Project No. 354522 is gratefully acknowledged.

OSSP contest

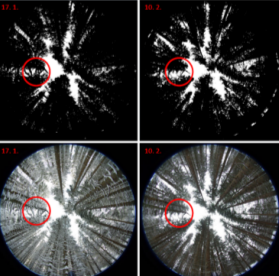

Conclusions

Conclusions

- The resulting values of the Leaf Area Index are **highly influenced** by meteorological conditions.
- The variance of the cumulative curves of the main snow interception model for the winter season 2020/21 is defined by the main equation, which is **based on the variable input values** of the vegetation structure.
- Despite the **impossibility of validating the model** due to the missing measured data of snow interception, the interception loss after correction of input snow density value **corresponds to the expected values**.
- Adapted** model of snow interception **reflects local conditions better**.
- The final values of the **interception loss** ranged from **19% to 38%**.
- The interception loss has stronger linear correlation with sum of snowfall than temperature

Uncertainties and possible errors in the study

- Accuracy of vegetation structure measurement
- Subjective hemispherical image evaluation in pre-processing of Leaf area index calculation
- Processing of vegetation structure input data → influence of meteorological conditions
- The lack of possibility to verify the results of the model by direct measurement

Contact to authors: Charles University, Department of Physical Geography and Geocology, Albertov 6, Prague 2, 128 43 Czech Republic. dominik.mika@natur.cuni.cz, michal.jenicek@natur.cuni.cz

Project No. 354522 is gratefully acknowledged.

- Snow interception is part of the snow storage of the basin
- **20-40%** of snowfall is captured by vegetation, and it is known as **interception loss**.
- In general, interception is **very difficult to measure directly**.
- Many models of interception is based on **vegetation structure** and **interception loss** is **higher** in winter due to snow precipitation.
- Many mountain basins are mostly covered by vegetation in Czechia

Research goals

- 1) To define vegetation structure by Leaf area index (LAI)
- 2) To adapt the Canadian model of snow interception for the Ptaci Brook basin
- 3) To model snow interception in several winter season in the Ptaci Brook basin, Sumava Mts., Czechia

Hydrologic processes in winter (USGS 2013)

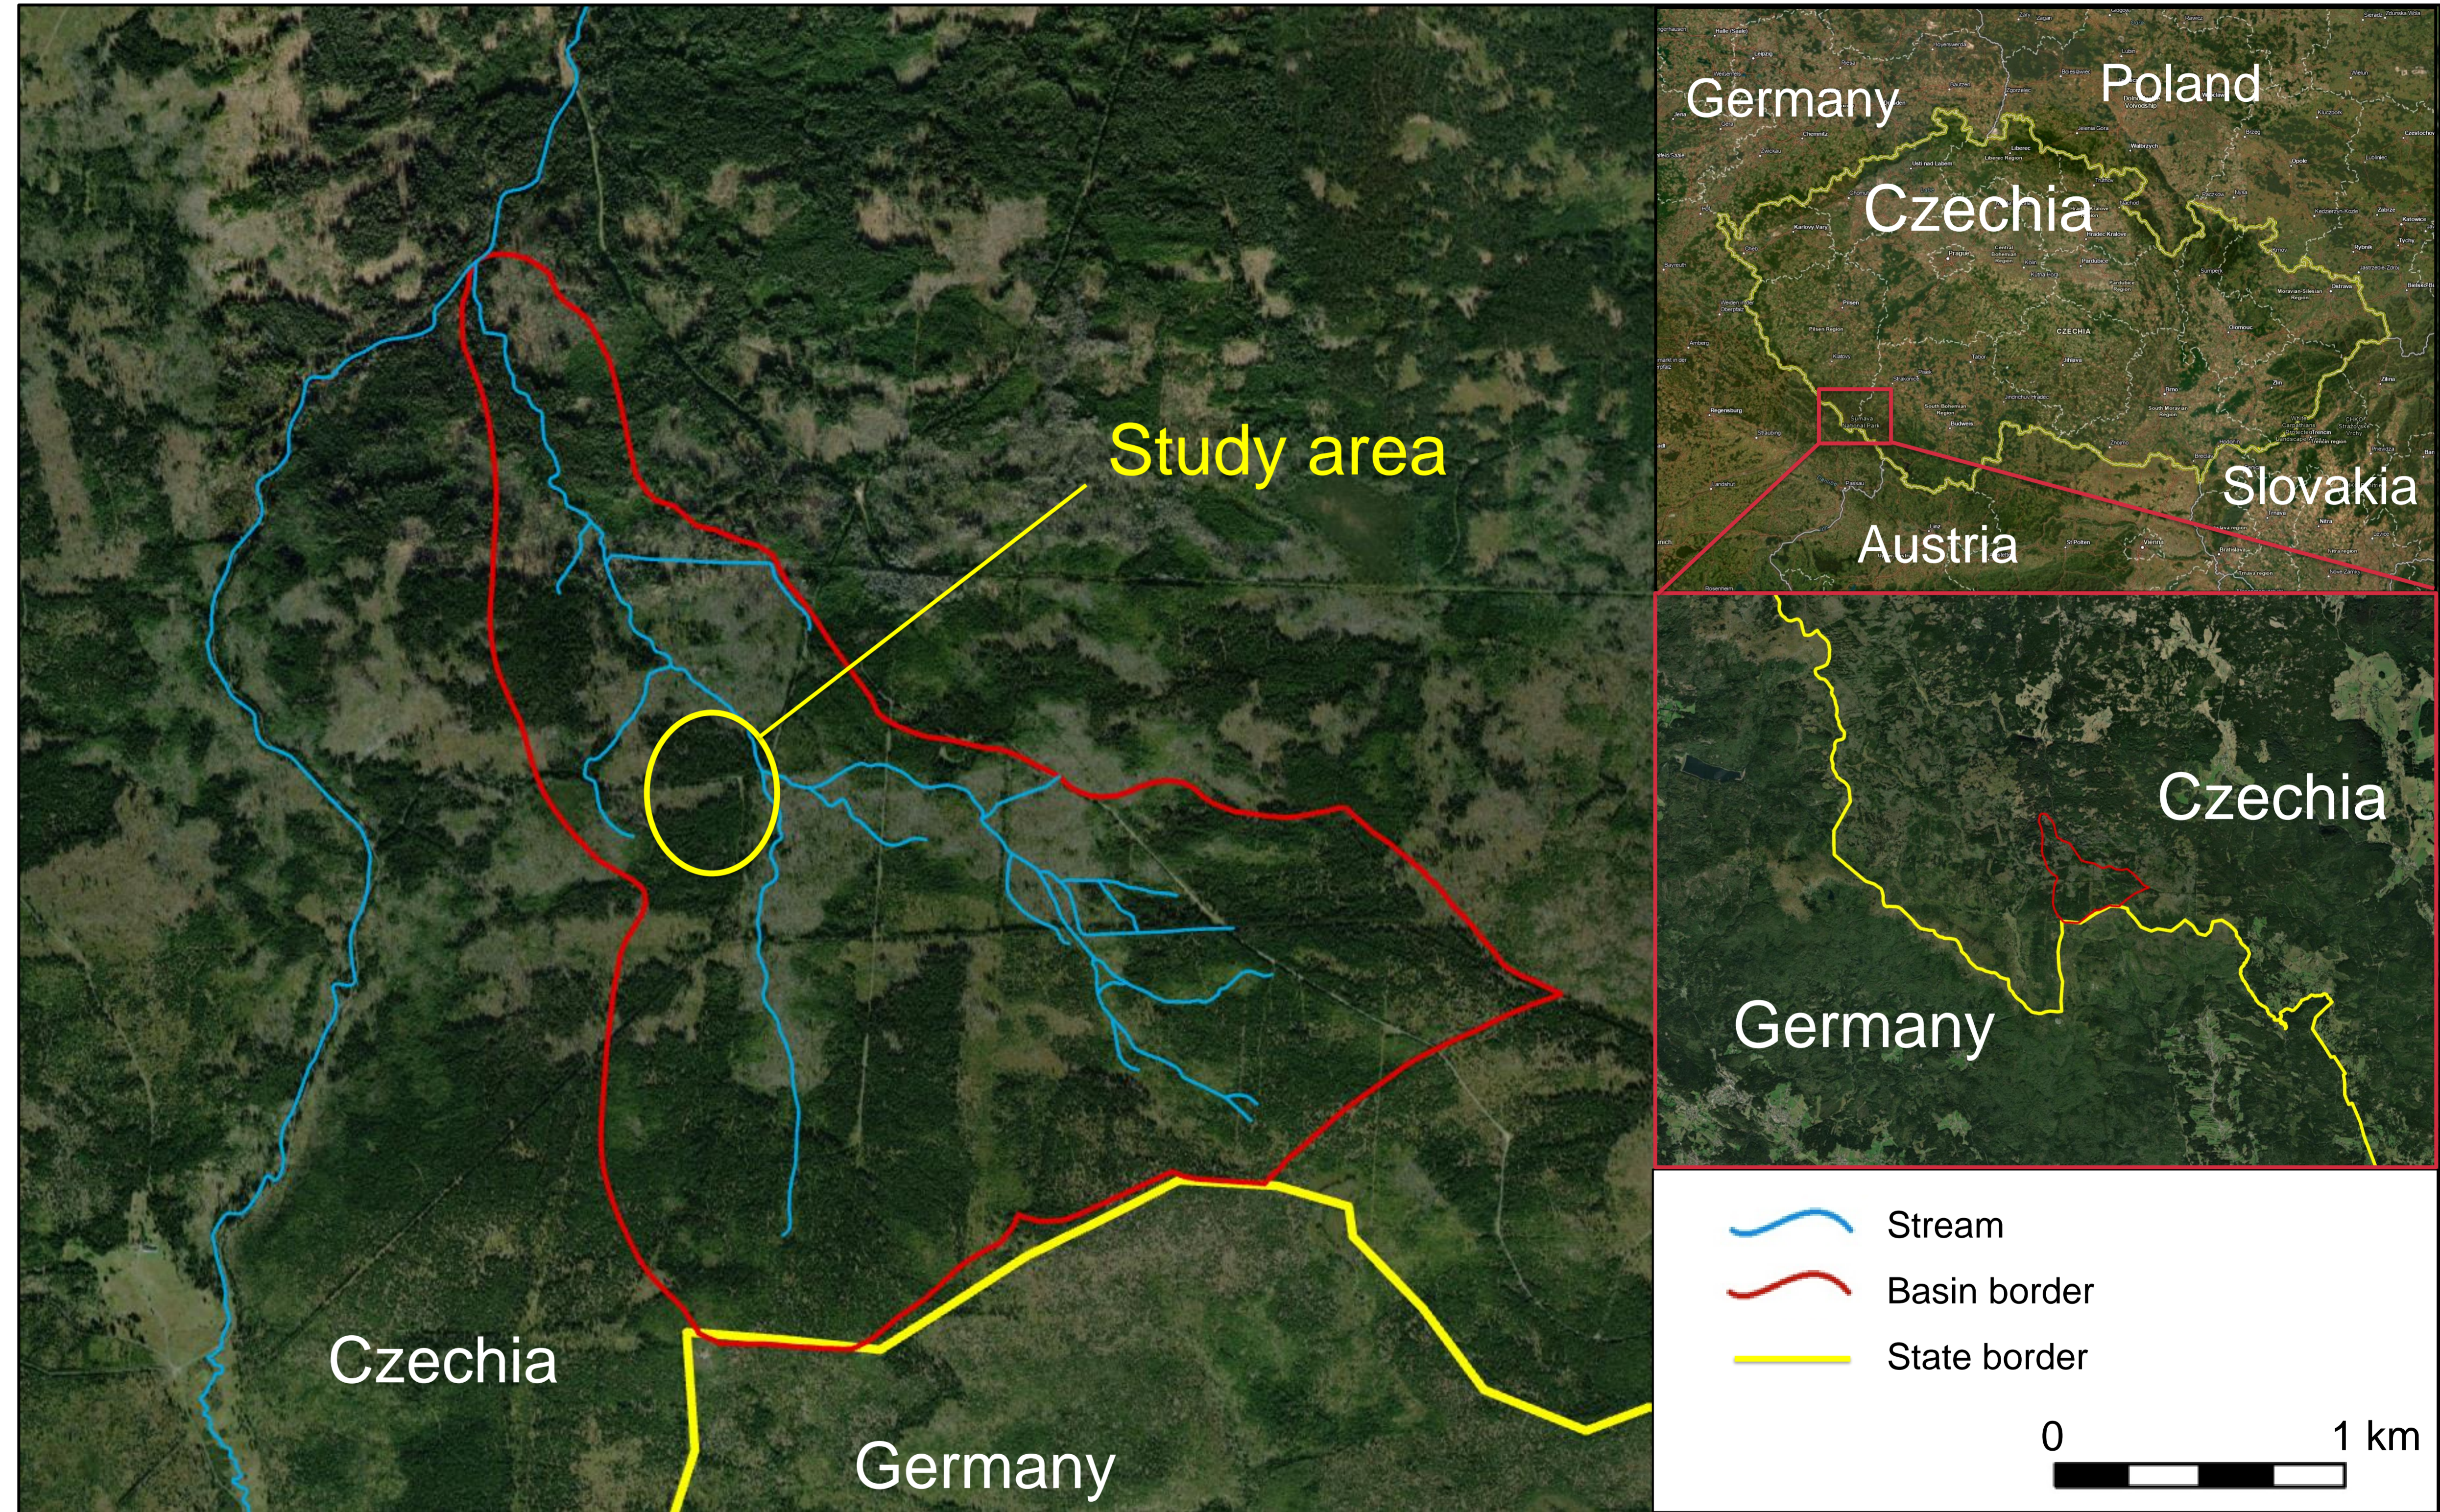

Study area

Basic characteristics of the Ptaci Brook basin

Stream length	4.3 km
Area	5.5 km ²
River network density	2.2 km/km ²
Mean elevation	1130 m a. s. l.
Total elevation difference	273 m
Mean annual temperature (1980-2013)	4.8 °C
Mean annual precipitation (1980-2013)	1202 mm

- Located in Šumava National Park
- season snowfall
 - about 16% of annual precipitation
- 70% covered by spruce forests
 - severely damaged (43%)
 - by the European spruce bark beetle (*Ips typographus*)
 - meteorological disturbances

Study area located in the middle of Sumava Mts. In Czechia near the borders with Germany

Methodology

Field measurements

- Winter season 2020/21
- Hemispherical images
- Different meteorological conditions
- 15 sites under the canopy

Hemispherical images from the research site in different weather conditions in winter season 2021

Capturing hemispherical images with a Pentax K-5 IIs digital mirror camera with fisheye lens

Canadian model of snow interception

by Hedstrom, Pomeroy (1998)

$$I = c(S_m - I_0) \left[1 - \exp\left(-\frac{C_c P}{S_m}\right) \right]$$

c – coefficient of snow unload from the canopy [dimensionless]

I_0 – initial intercepted snow load [mm]

C_c – canopy closure [dimensionless]

P – snowfall [mm]

S_m – maximum canopy snow load $\longrightarrow S_m = S_b(LAI)(0.27 + 46/\rho_s)$

by Schmidt, Gluns (1991)

S_b – maximum snow load of branch [spruce – 5.9 mm]

LAI – Leaf area index

ρ_s – density of snow [$\text{kg}\cdot\text{m}^{-3}$]

Simple equation of snow interception

$$I = P_c - P_f$$

P_c – total snowfall on open area [mm]

P_f – total snowfall under the canopy [mm]

! There were NO possibility to measure snow interception directly

- We do not have a snow interception measurement device.
- All possible ways of direct measurements are not „nature friendly“ – study area is in Šumava National Park

Density of snow

- Equation used in Canadian model (Schmidt, Gluns 1991)

$$\rho_s = 67.92 + 51.25 * e^{\left(\frac{T_{air}}{2.59}\right)}$$

- Adapted eq. on local conditions (Penaz 2022)

$$\rho_s = 0.2102 * e^{(T_{air}*0.1013)}$$
