# Dramatic changes have occurred in mitigation policy factors worldwide

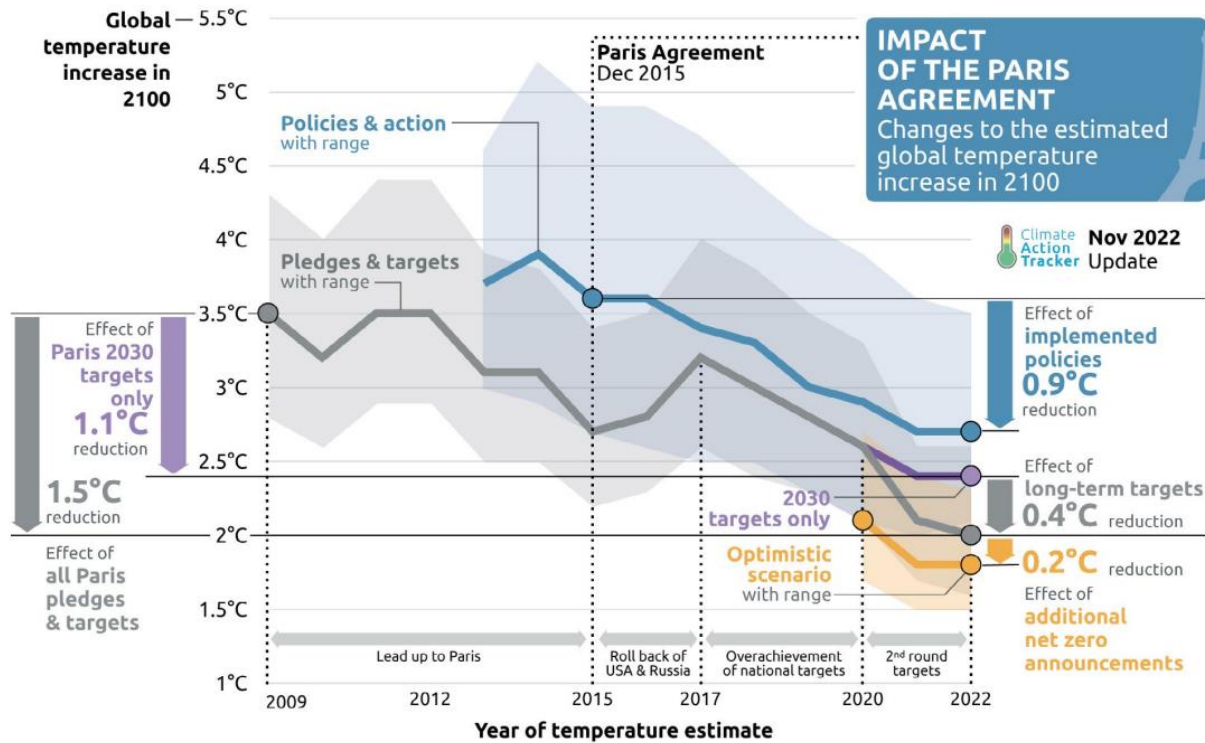

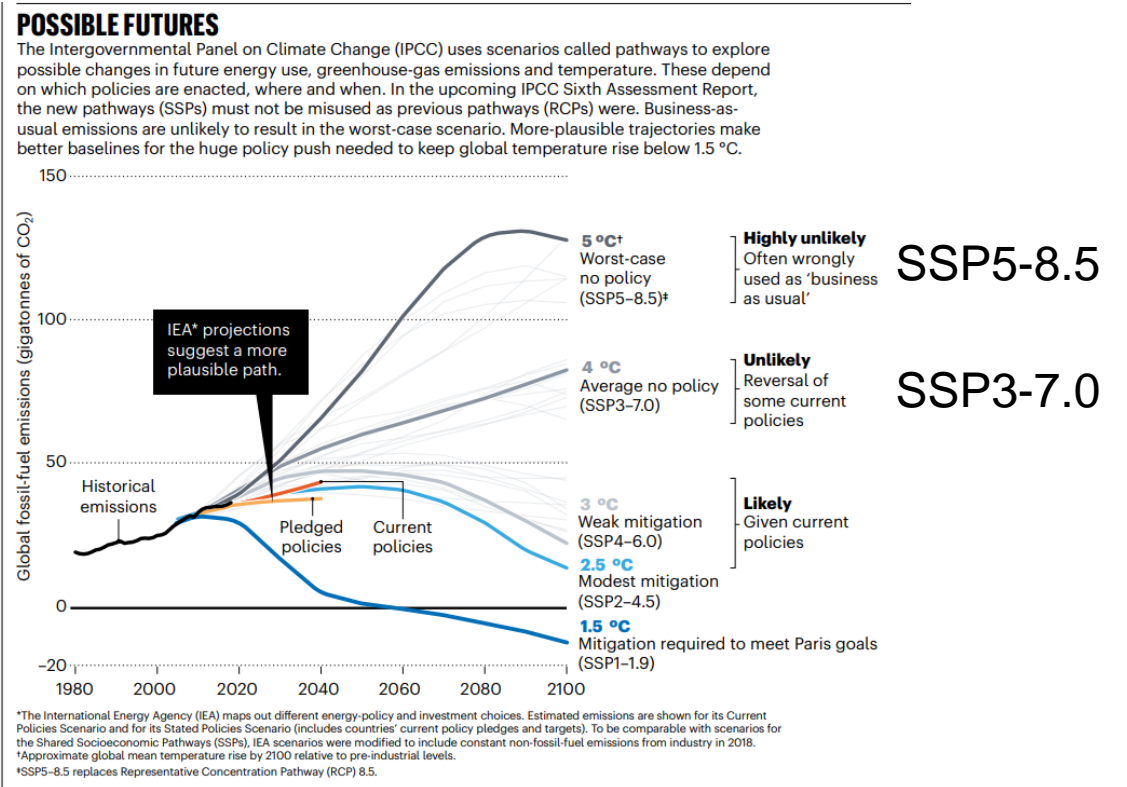

Figure 5: Impact of the Paris Agreement on the estimated global warming increase in 2100. Figure shows the estimates of the Climate Action Tracker from 2009-2022 for 'pledges and targets' and 'policies & action'.<sup>6</sup>

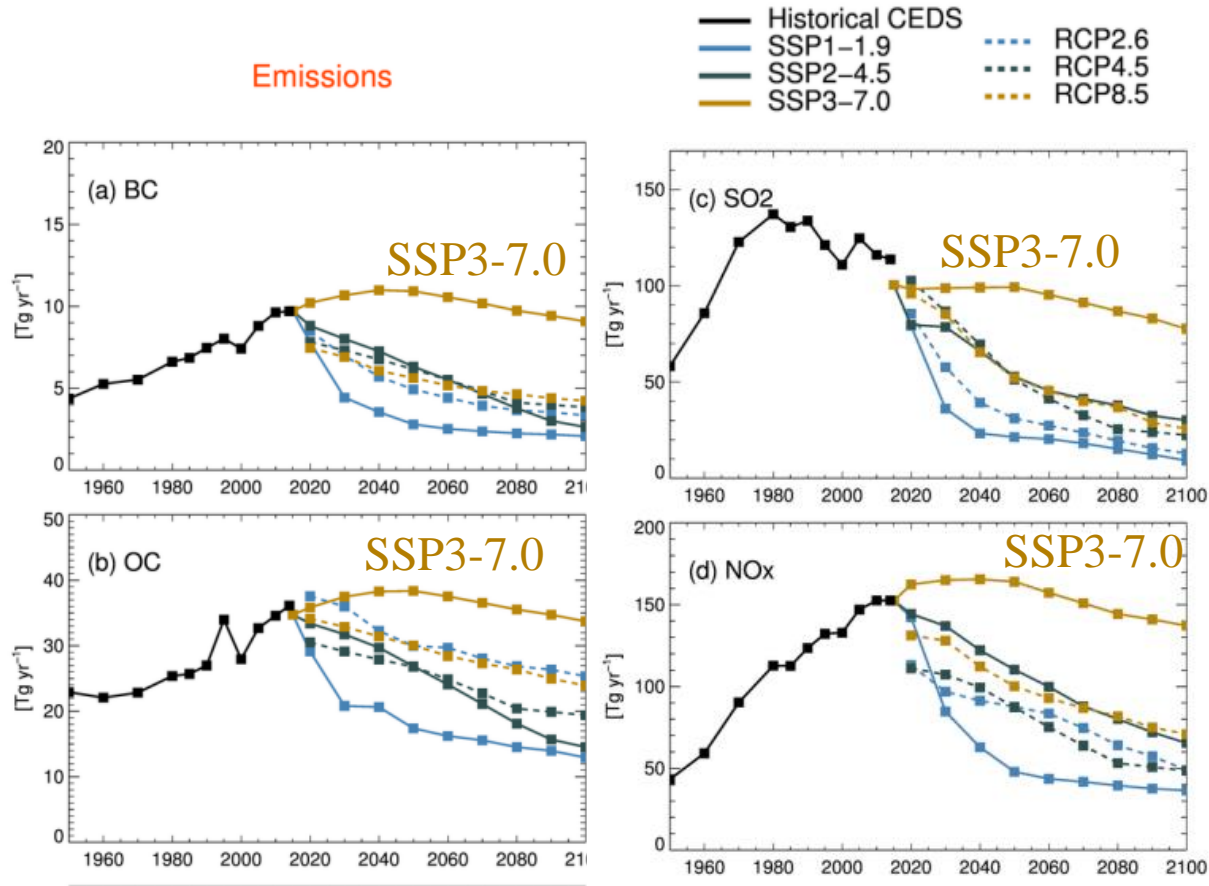

Climate Action Tracker (2022)

Hausfather and Peters (2020, Nature)

- Mitigation efforts after the 2015 Paris Agreement have made the upper-end scenario of the future GHG concentration (SSP5-8.5) highly unlikely.
- Therefore the second highest scenario (SSP3-7.0) has recently received attention as an alternative high-end scenario for impact studies.
- However, we are concerned about that IAV researchers do not well recognize the 'distinctiveness' of SSP3-7.0

# Distinctive high aerosol emission

Lund et al. (2017, ACP)

- Aerosol emissions increase or change little in SSP3-7.0 due to the assumption of a lenient air quality policy, while they decrease in the other SSP-RCPs of CMIP6 and all the RCPs of CMIP5.
- This distinctive high-aerosol-emission design of SSP3-7.0 was intended to enable AerChemMIP to investigate the consequences of continued high levels of aerosol emissions on climate.

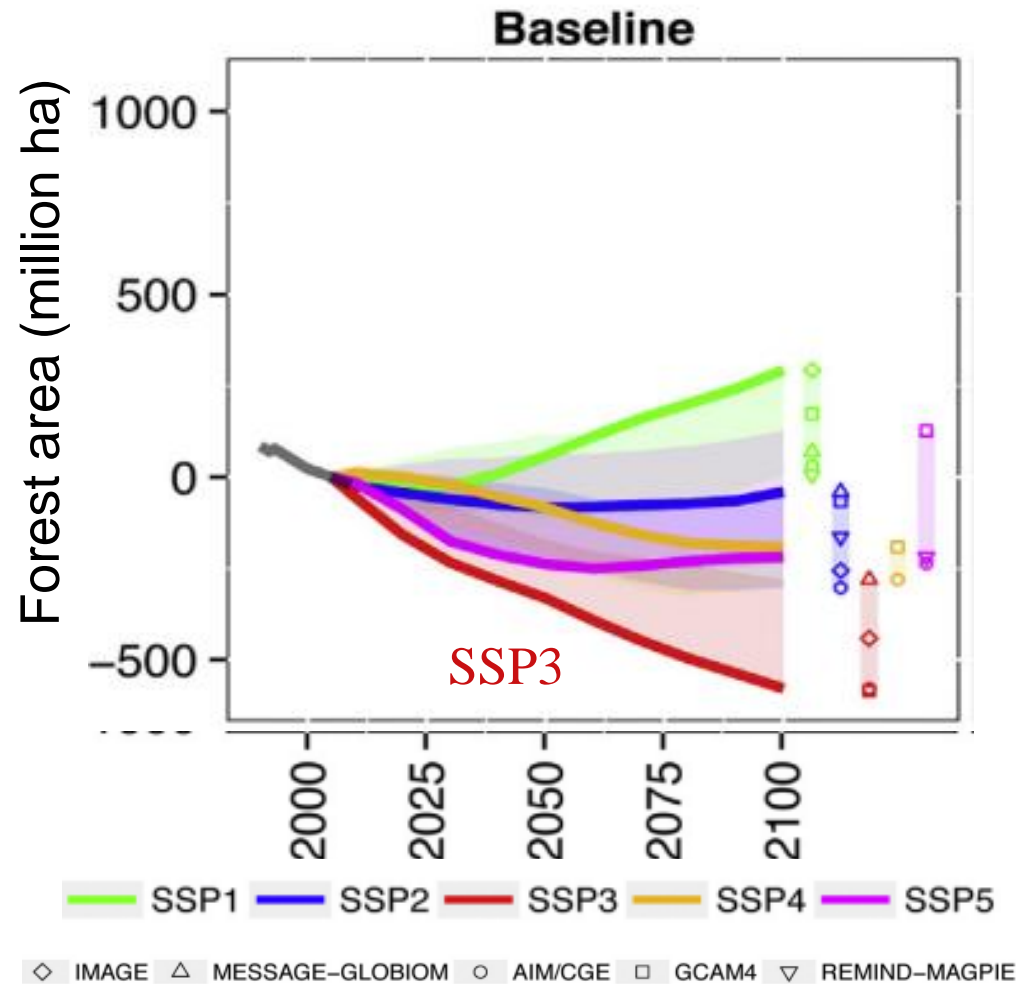

B. C. O'Neill et al.: The Scenario Model Intercomparison Project (ScenarioMIP) for CMIP6

3471

Table 2. ScenarioMIP experimental design.

Scenario name	Forcing category	2100 forcing <sup>1</sup> (W m <sup>-2</sup> )	SSP	Use by other MIPs <sup>2</sup>
Tier 1 <sup>3</sup>				
SSP5-8.5	High	8.5	5	C <sup>4</sup> MIP, GeoMIP, ISMIP6, RFMIP
SSP3-7.0	High	7.0	3	AerChemMIP, LUMIP
SSP2-4.5	Medium	4.5	2	VIACS AB, CORDEX, GeoMIP, DAMIP, DCPD
SSP1-2.6	Low	2.6	1	LUMIP

O'Neill et al. (2016, GMD)

- Decreases in forest area were also substantial in SSP3-7.0, unlike in the other SSP-RCPs.
- This design enables LUMIP to analyse the climate influences of extreme land-use and land-cover changes.

B. C. O'Neill et al.: The Scenario Model Intercomparison Project (ScenarioMIP) for CMIP6

3471

Table 2. ScenarioMIP experimental design.

Scenario name	Forcing category	2100 forcing <sup>1</sup> (W m <sup>-2</sup> )	SSP	Use by other MIPs <sup>2</sup>
Tier 1 <sup>3</sup>				
SSP5-8.5	High	8.5	5	C <sup>4</sup> MIP, GeoMIP, ISMIP6, RFMIP
SSP3-7.0	High	7.0	3	AerChemMIP, LUMIP
SSP2-4.5	Medium	4.5	2	VIACS AB, CORDEX, GeoMIP, DAMIP, DCCP
SSP1-2.6	Low	2.6	1	LUMIP

O'Neill et al. (2016, GMD)

- The IAM community (Prof. S. Fujimori), who developed the SSP-RCPs, did not anticipate the limelight on SSP3-7.0 for IAV studies because
  - SSP3-7.0 was the distinctive scenario
  - there were low (SSP1-2.6), medium (SSP2-4.5) and high (SSP5-8.5) scenarios available for investigation of scenario uncertainties in impact assessments.
- The IAM community also expected that the influences of extreme scenarios of aerosols and land-use land-cover change on climate were small,
  - but there was no evidence supporting that assumption.
  
- At least, we can demonstrate notable effects of the distinctive aerosol emissions in SSP3-7.0 on climate projections.

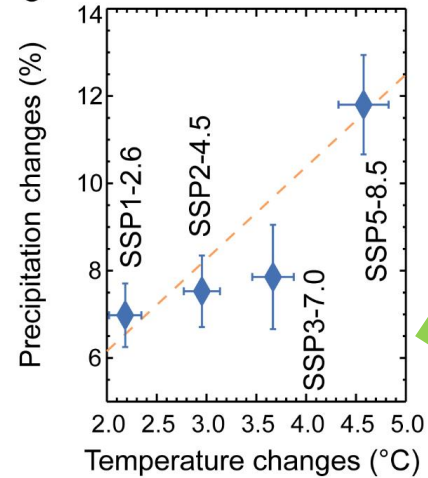

# Aerosols can efficiently reduce precipitation increases in SSP3-7.0

(6/7)

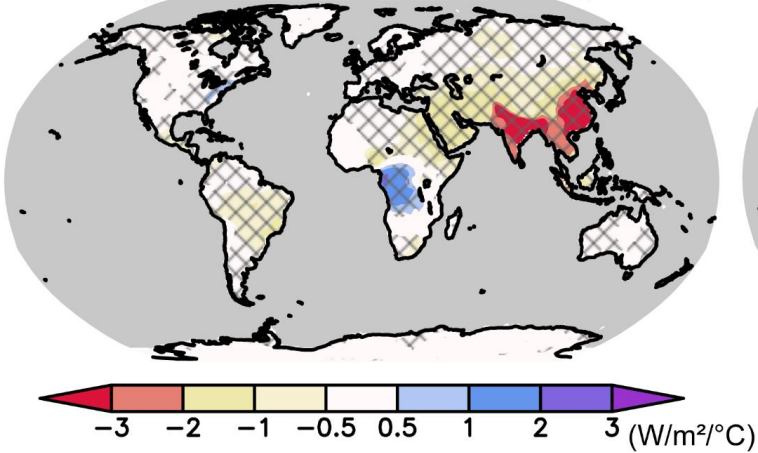

(a) Changes in the global mean temperature and precipitation

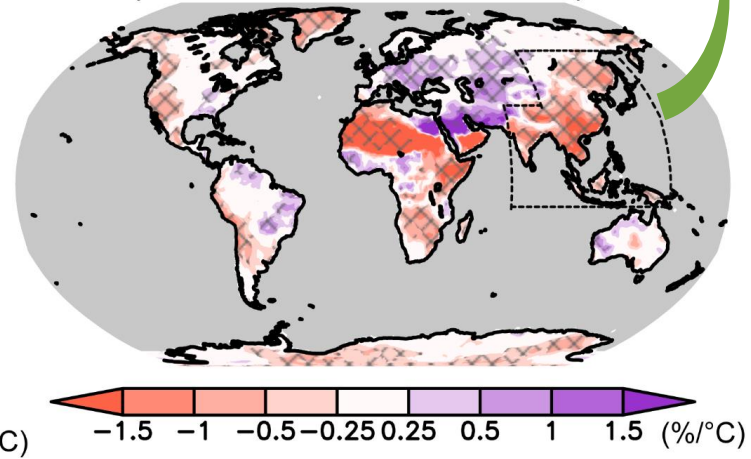

(b) Changes in temperature and precipitation averaged over the selected land region

(c) Diff. of downward SW radiation sensitivity (SSP3-7.0 minus SSP5-8.5)

(d) Diff. of precipitation sensitivity (SSP3-7.0 minus SSP5-8.5)

- Whereas the global mean temperature warming is greater in SSP-RCPs with larger GHG emissions, the increases in the global mean precipitation of SSP3-7.0 are similar to those of SSP2-4.5. Large aerosol emissions in SSP3-7.0 suppress future increases in precipitation.
- For changes in downward shortwave radiation at the surface per degree global warming, differences between SSP3-7.0 and SSP5-8.5 are large in eastern, southeastern and southern Asia due to the higher aerosol emissions in SSP3-7.0 in those areas. Negative anomalies of downward shortwave radiation affect the surface energy balance, resulting in suppression of evapotranspiration and precipitation.
- Future increases in precipitation are lowered around those areas in SSP3-7.0 and are similar to those in SSP2-4.5, whereas temperature increases are larger in SSP3-7.0 than in SSP2-4.5.

No IAV studies have investigated how these distinct changes in shortwave radiation and precipitation in SSP3-7.0 can affect impact assessments

# Recommendations

## For the IAV community

- It is useful to compare impacts per degree global warming between SSP3-7.0 and SSP5-8.5 to investigate the effects of aerosols on impacts.
- Although SSP5-8.5 was recently labelled the “unlikely worst case scenario”, RCP8.5 was used as the upper-end scenario before the Paris Agreement. Therefore, we can examine the possible benefits of mitigation efforts after the Paris Agreement by comparing the CM and impact model simulations under SSP5-8.5 and those under the other SSP-RCPs.

## For the IAM community

- ScenarioMIP is now discussing the scenario design for CMIP7.
- We recommend excluding scenarios with extreme policies of aerosols and land-use land-cover changes from Tier 1 of ScenarioMIP/CMIP7 and instead including them in AerChemMIP and LUMIP.

# ssp370-lowNTCF of AerChemMIP (a variant of SSP3-7.0 with a cleaner air quality policy except for methane)

The 2015-2050 linear trends of precipitation under SSP3-7.0 are lower than those under SSP3-7.0-lowNTCF.

The median values of the reduction rate are 39% and 53% for the global mean and selected area mean precipitation trends, respectively.

Unfortunately, the end time of ssp370-lowNTCF was set to the middle of this century (not 2100).
