

Understanding the low-frequency electrical properties of ice–water interfaces from laboratory and field experiments

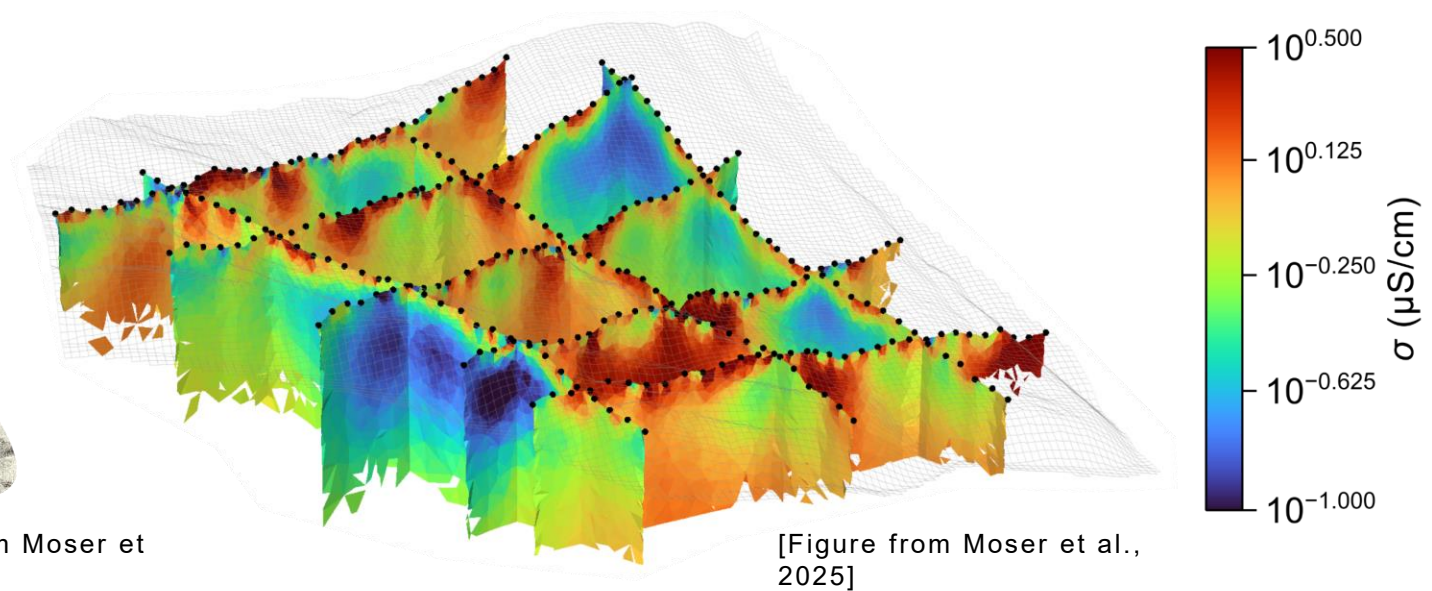

Clemens Moser¹, Alexander Bast^{2,3}, Sophie Francis¹, Matthias Halisch⁴, Christian Hauck⁵, and Adrián Flores Orozco¹

3D orthomosaic

3D conductivity model

Electrical conductivity can be ambiguous in alpine permafrost
 → Use of **low-frequency polarization effects as complementary parameter**

Electrical methods for permafrost investigations

3D orthomosaic

[Orthomosaic from Moser et al., 2025]

3D conductivity model

[Figure from Moser et al., 2025]

- **Geophysical methods** can provide information about **hydrogeological properties** (e.g., ice and water content) in the subsurface.
- Particularly, **electrical conductivity** is a well established parameter to **distinguish between frozen and unfrozen areas**.
- However, using **conductivity** alone may be **ambiguous** (rocks and ice can be both highly resistive).

Polarization effects in frozen materials

Pure ice

[Figure from Petrenko, 1993]

Ice in solid rocks / sediments

[Data from Limbrock et al., 2025]

Low-frequency effects

[Figure from Maierhofer et al., 2026]

This study

Hypothesis: The electrical double layer (EDL) formed at the ice–water interface results in a low-frequency polarization response ($f < 1$ kHz).

Three experiments at different scales to test this hypothesis.

Exploitation of high-frequency effect at the field scale:

- Grimm & Stillman, 2015
- Mudler et al., 2024
- Sugand et al., 2026

Spectral Induced Polarization (SIP) method

Impedance measurement

Impedance: $Z^* = \frac{V^*}{I^*} = |Z^*|e^{i\varphi}$

– **Magnitude:** $|Z^*| = \frac{|V^*|}{|I^*|}$

– **Phase:** $\varphi = 2\pi \frac{\Delta t}{T_p}$

Z^* ... Impedance (Ω)

V^* ... Voltage (V)

I^* ... Current (A)

φ ... Phase (rad)

i ... Imaginary number

Complex conductivity

[Figure from Binley & Slater 2020]

$$\sigma^* = \sigma' - i\sigma'' = |\sigma^*|e^{i\varphi}$$

σ' ... Real part (S/m)

σ'' ... Imaginary part (S/m)

$|\sigma^*|$... Magnitude (S/m) $\sim \sigma'$

φ ... Phase angle (mrad) $\sim \sigma''/\sigma'$

(3) Rock samples experiment

Centimeter scale

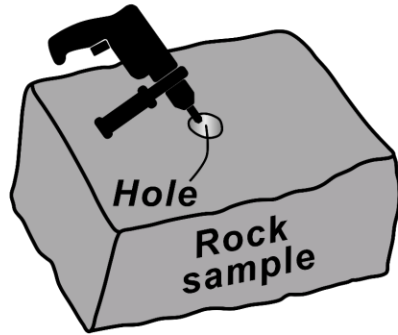

Ice-filled hole

Experiment setup

(1) Drilling a hole

(2) Saturate the sample in a vacuum chamber

(3) Adhering medical gel electrodes

(4) Sample in climate chamber for SIP measurements

(5) SIP data collection with air-filled hole

(6) Fill hole with water of certain σ_f

(7) Water in the hole freezes

(8) SIP data collection with ice-filled hole

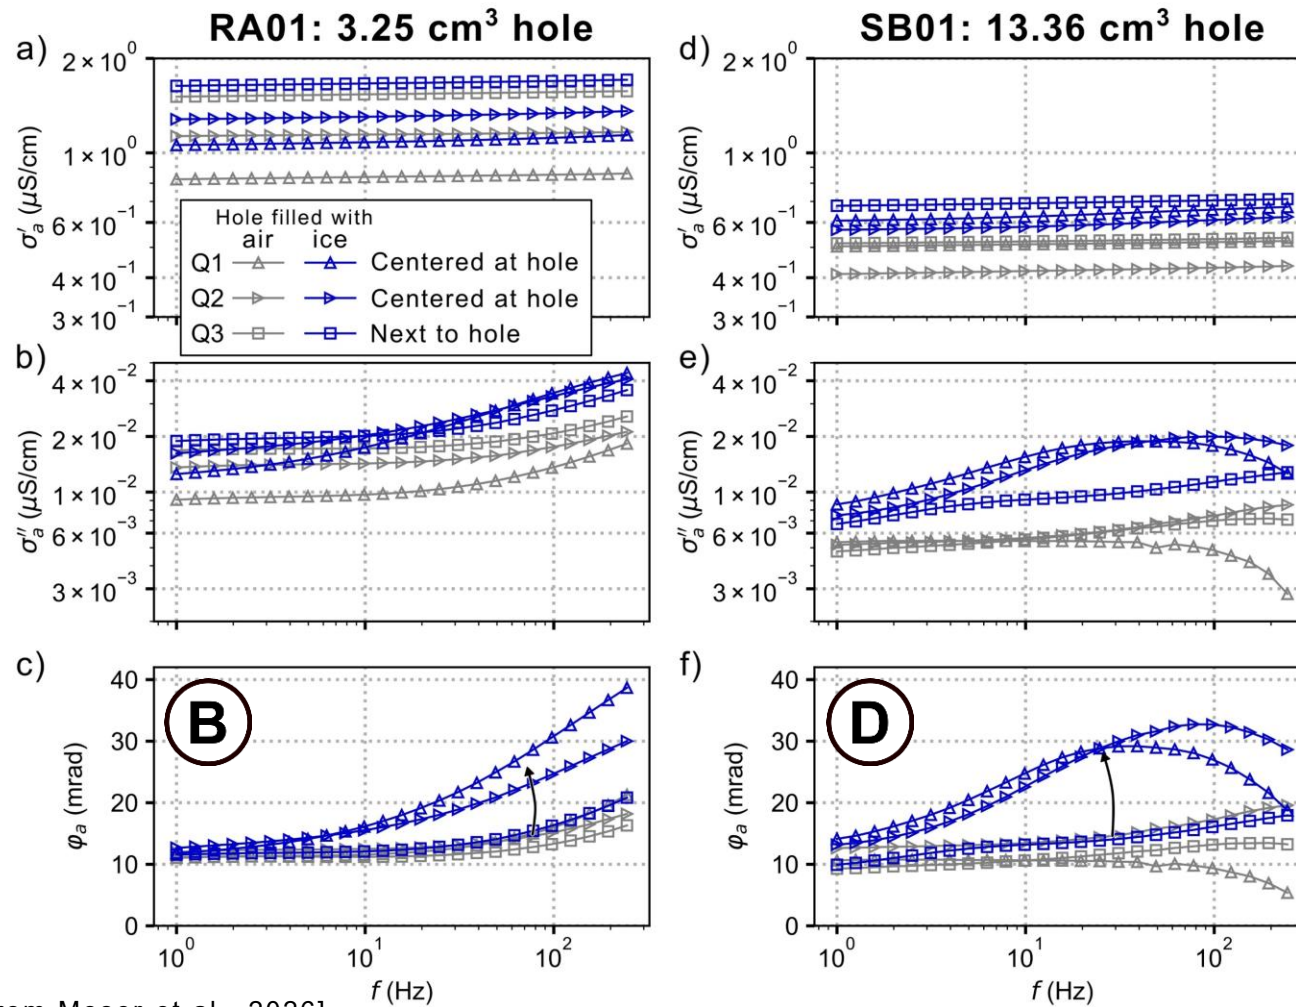

* Portable Field/Lab Spectral Induced Polarization (SIP) Unit (PSIP)

Rock samples

Polarization effects under thermal equilibrium

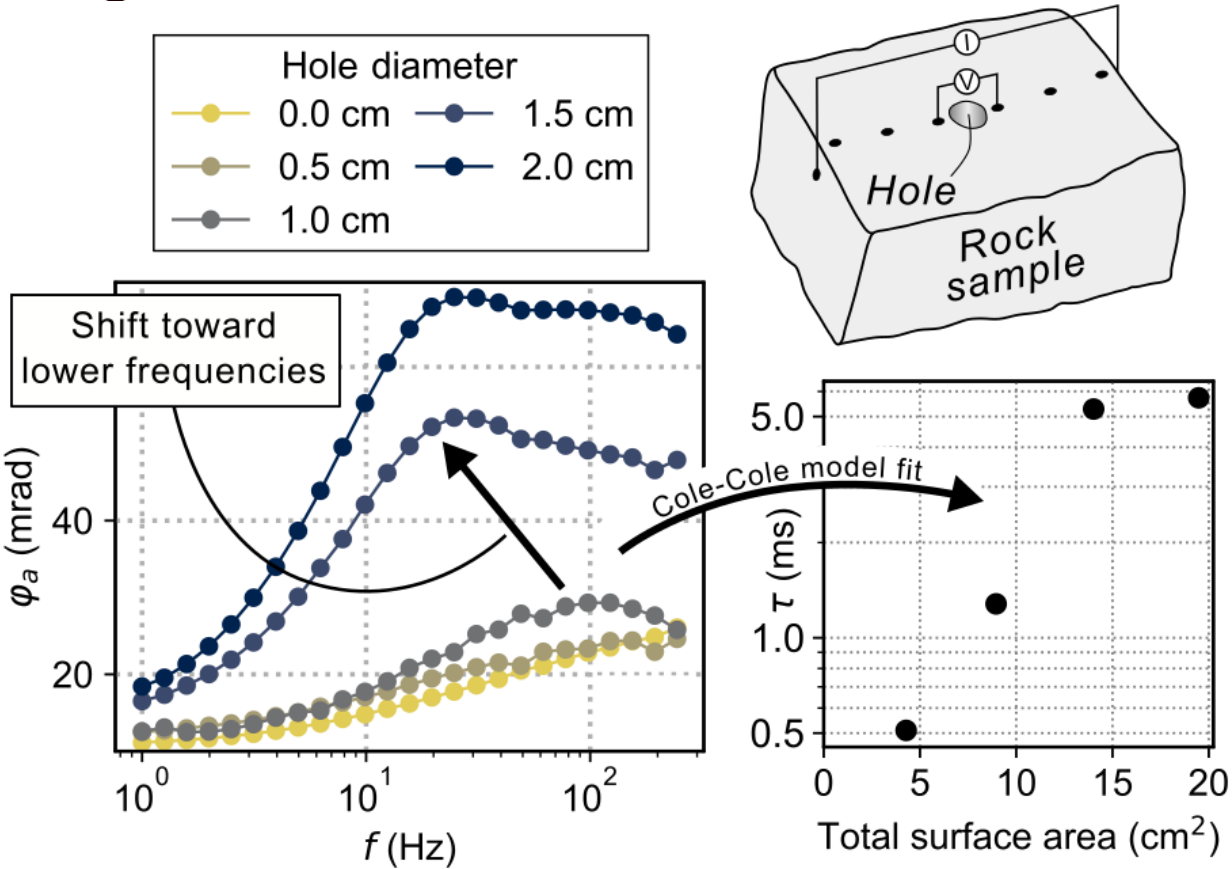

[Figure from Moser et al., 2026]

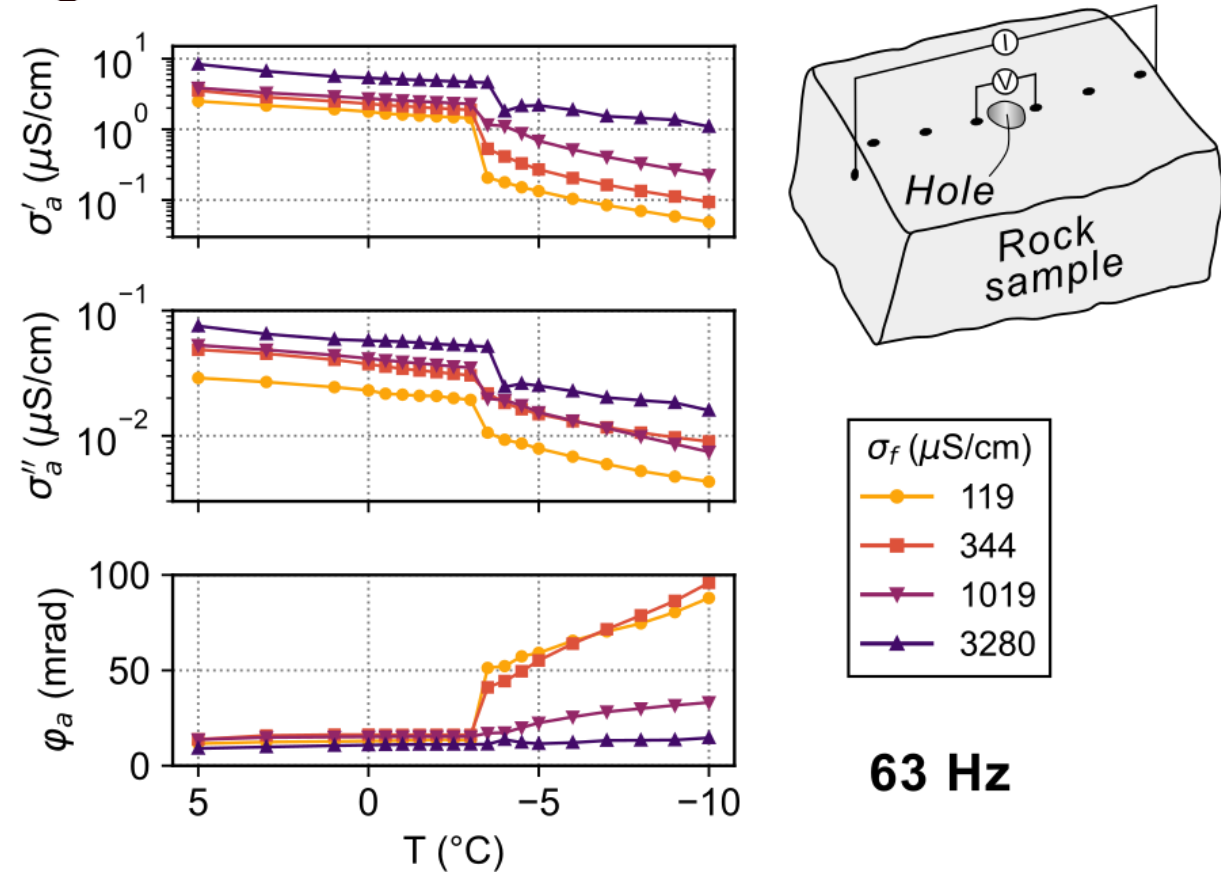

Polarization effects under thermal equilibrium

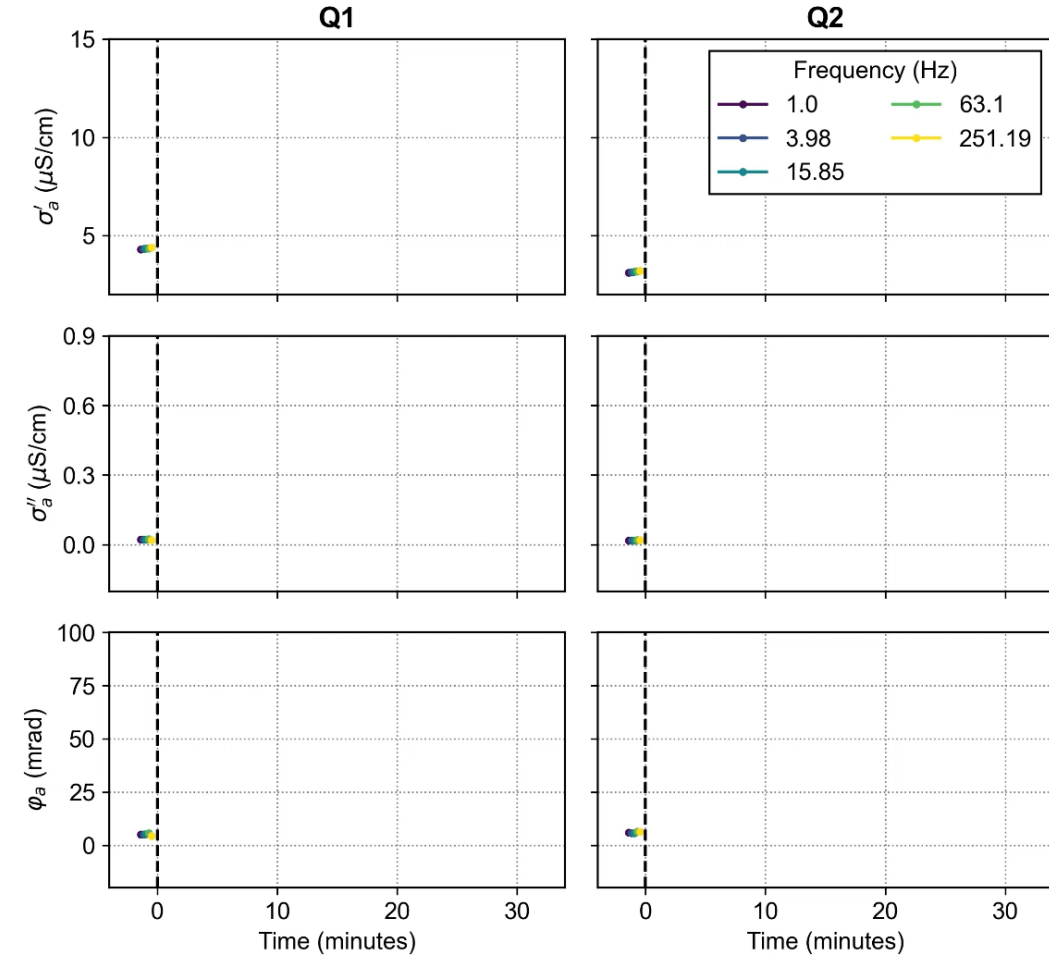

D Effect of varying hole diameter

D Effect of varying salinity

Polarization effects during ice formation

Description of the quadrupoles

Quadrupole 1 (Q1):

Quadrupole 2 (Q2):

Sensitivity analysis

Quadrupole 1

Q1 is positively (and highly) sensitive to blank ice feature

Resistive and polarizable feature results in:

- Large $|\rho_a^*|$ increase
- φ_a increase (**positive IP effect**)

2 regions:

- (1) Rock material: $\rho = 17000 \Omega\text{m}$; $\varphi = -8 \text{ mrad}$
- (1) Ice material (anomaly): $\rho = [10^2:10^6] \Omega\text{m}$; $\varphi = [-200, -500, -800] \text{ mrad}$

Quadrupole 1 (Q1):

Quadrupole 2

Quadrupole 2 (Q2):

Q2 is negatively (and less) sensitive to blank ice feature

Resistive and polarizable feature results in:

- Slight $|\rho_a^*|$ decrease
- φ_a decrease (**negative IP effect**)

Magnitude	Phase	Phase used in synthetic model
Orange	●	$\varphi_2 = -200 \text{ mrad}$
Red	●	$\varphi_2 = -500 \text{ mrad}$
Purple	●	$\varphi_2 = -800 \text{ mrad}$

Polarization effects during ice formation

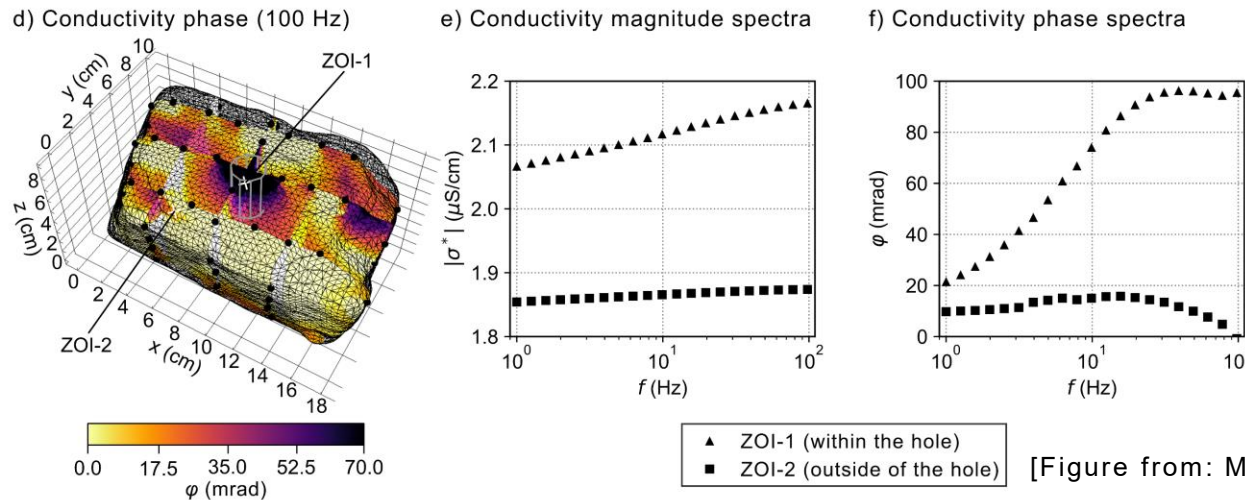

Temperature change over time

Polarization effects during ice formation

Imaging inversion results

- **Conductivity magnitude:**
 - Almost no contrast between ice-filled hole and frozen rock material
- **Conductivity phase:**
 - Strong phase anomaly at position of ice-filled hole at $f = 1\text{--}100\text{ Hz}$

[Figure from: Moser et al., 2026]

Imaging inversion results

CT scan

Vertical slice

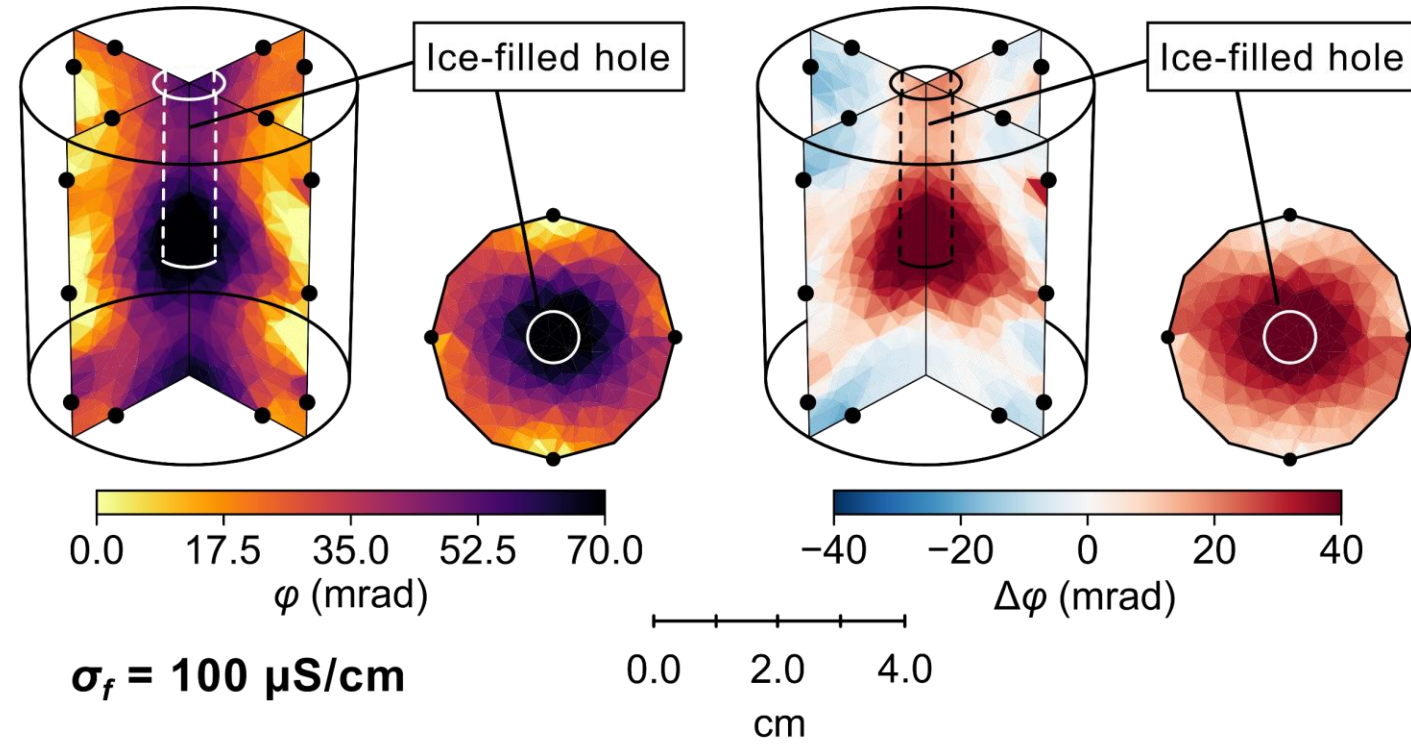

Horizontal slice

3D inversion result at 15 Hz

Ice-filled state

Difference between ice- and air-filled state

Conclusions experiment 1

- 1) **Blank ice features** in solid rock discontinuities **polarize** between 1–100 Hz in thermal equilibrium.
- 2) The polarization response **increases** with **increasing hole diameter**, and in turn, with increasing ice volume.
- 3) Even stronger **polarization effect during the formation of ice** due to charge separation between ice and liquid water (Workman-Reynolds-Freezing-Potential effect).

(2) Tank experiment

Decimeter scale

Experiment overview

Picture

Sketch

Experimental setup

- **Tank dimensions:** 68.0 × 47.9 × 3.0 cm
- **Box with dry ice:**
 - 15.0 cm diameter
 - 4.0 cm distance from tank edge
- **SIP measurements:**
 - 52 electrodes with 4.4 cm spacing
- **Temperature sensors:**
 - Sensor 1: 1.0 cm distance from box
 - Sensor 2: 2.5 cm distance from box
- **Optical camera:** Continuous video
- **Infrared camera:** Single shot at ice maximum

Box with dry ice (covered)

Optical camera

Temp. sensors

Porosity / Water content: 34.64 %

Fluid conductivity: ~330 μS/cm

Temperature

Temperature over time measured by temp. sensors

- $T < 0\text{ °C}$
 - 1 cm dist.: ~2.5 h after first dry ice, ~5 h after dry ice
 - 2.5 cm dist.: ~4.5 h after dry ice, ~3 h after last dry ice

Infrared pictures

SIP data collection

Numerical modeling

Electrode combinations tested

- Dipole-dipole (DD) sk-3 all levels
- Multiple-Gradient (MG)
- DD sk-0, DD sk-1, DD sk-2 only 8 levels

Data visualizations

Only inline data*:

Time-lapse inversion results

t0: 2026-03-25 12:02:27

Frequency: 7.5 Hz

Preliminary observations:

- **Period 1 (without ice):** Low contrast in $|\rho^*|$ and φ between water-saturated gravels and resistive air-filled box
- **Period 2 (freezing process):** Increasing $|\rho^*|$ and φ in ice-saturated anomaly
- **Period 3 (thawing):** Decreasing $|\rho^*|$ and φ during thawing

PSIP profiling

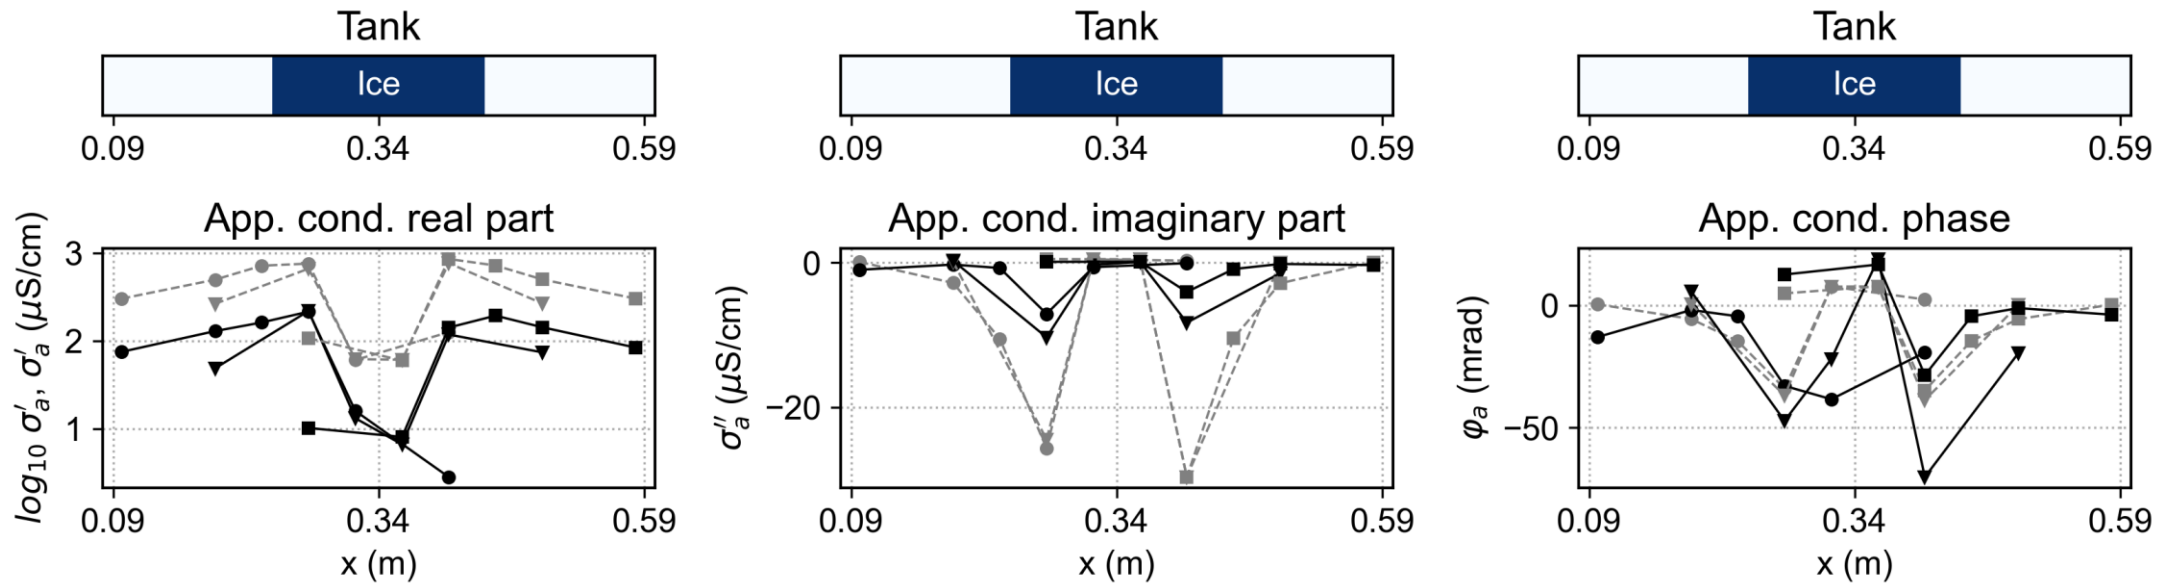

Configuration

Symbology

Results

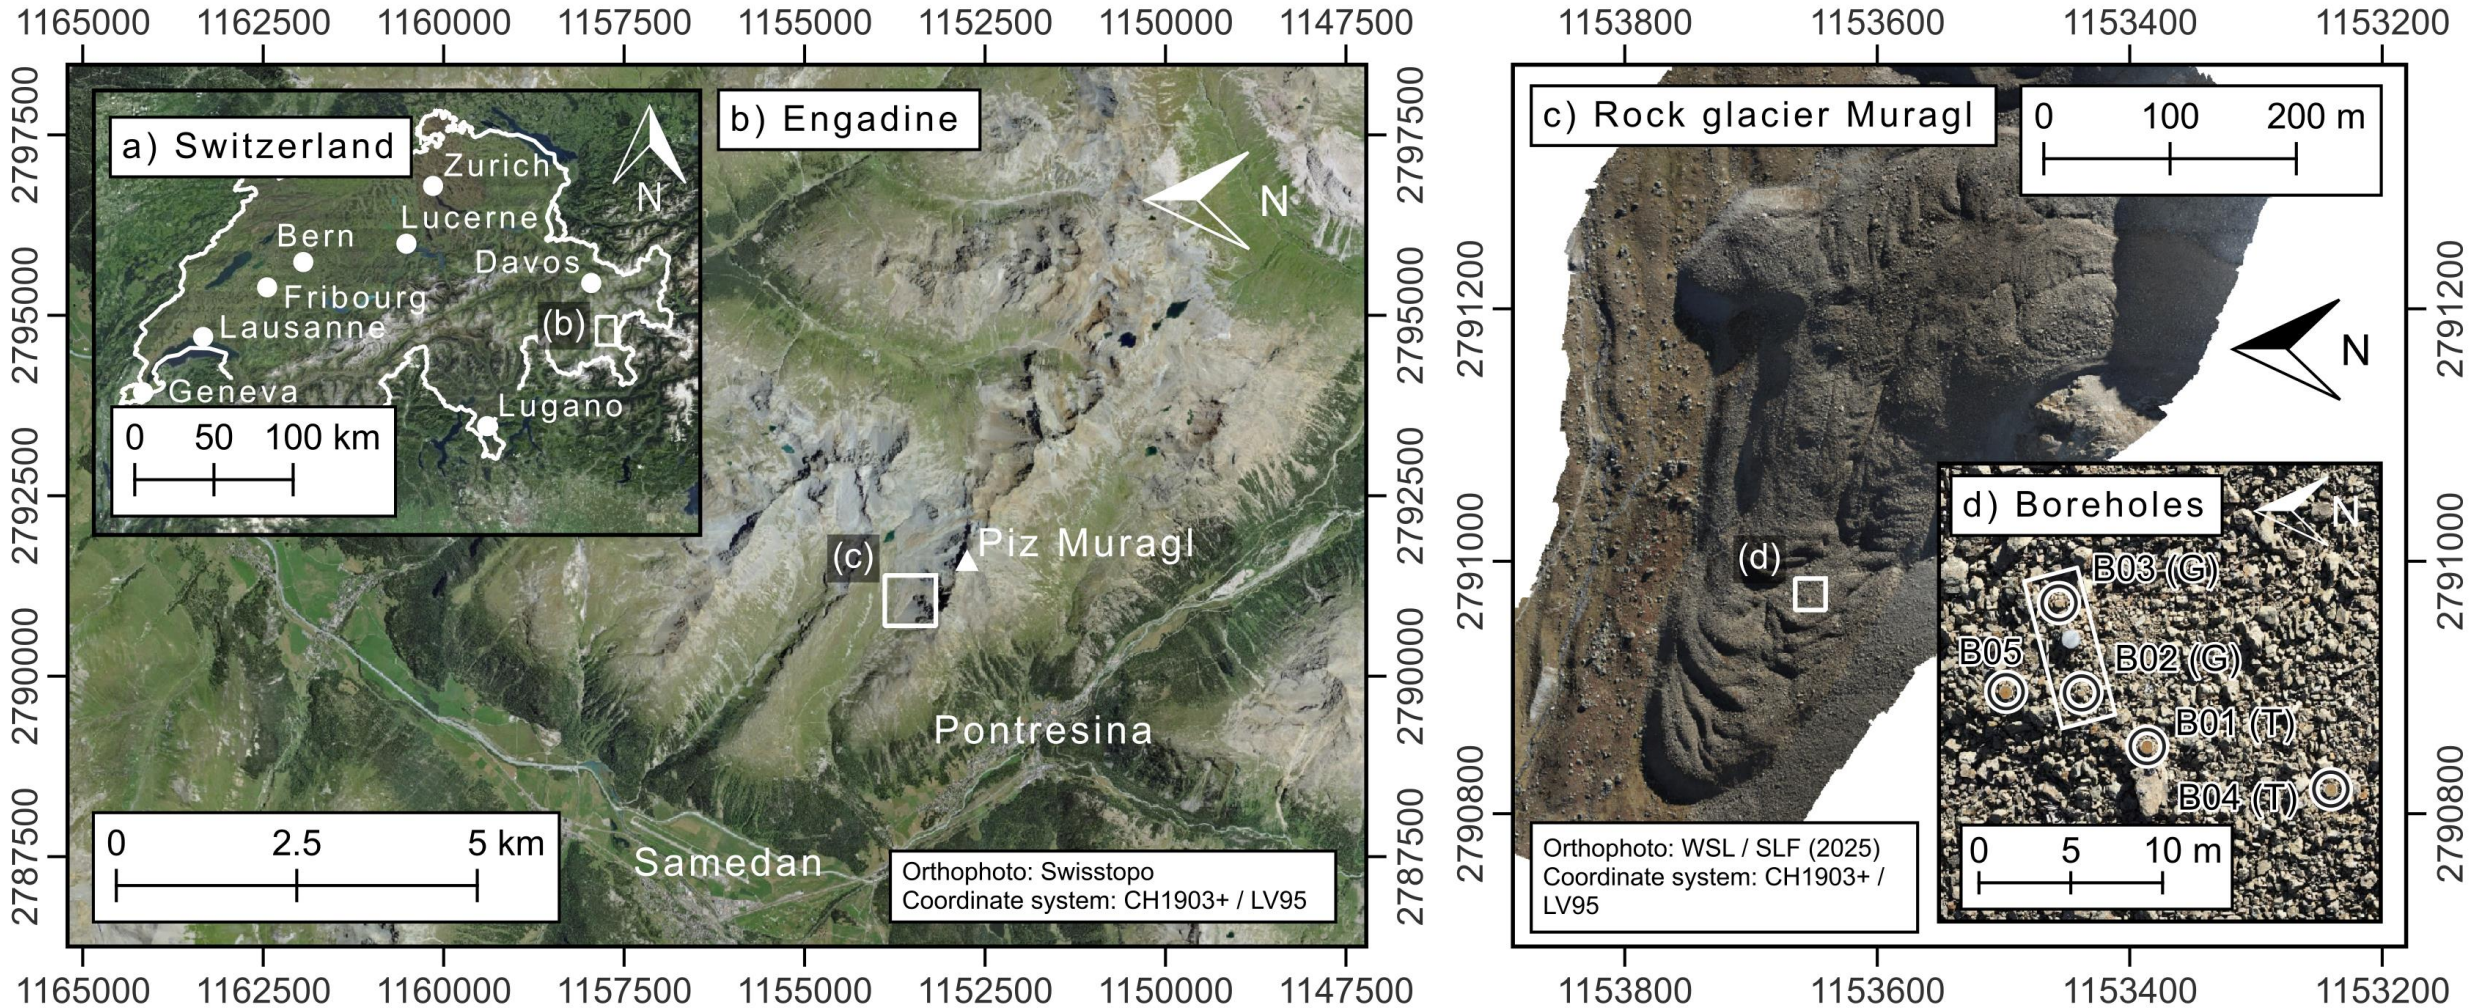

Conclusions experiment 2

- 1) **Low-frequency (1–100 Hz) polarization** effects can be also observed in **frozen sediments**
- 2) Frozen sediments act as a **resistive and polarizable anomaly**, which can result in **negative IP effects**

Study area: Rock glacier Muragl

Borehole temperatures

Oct. 2024 – Oct. 2025

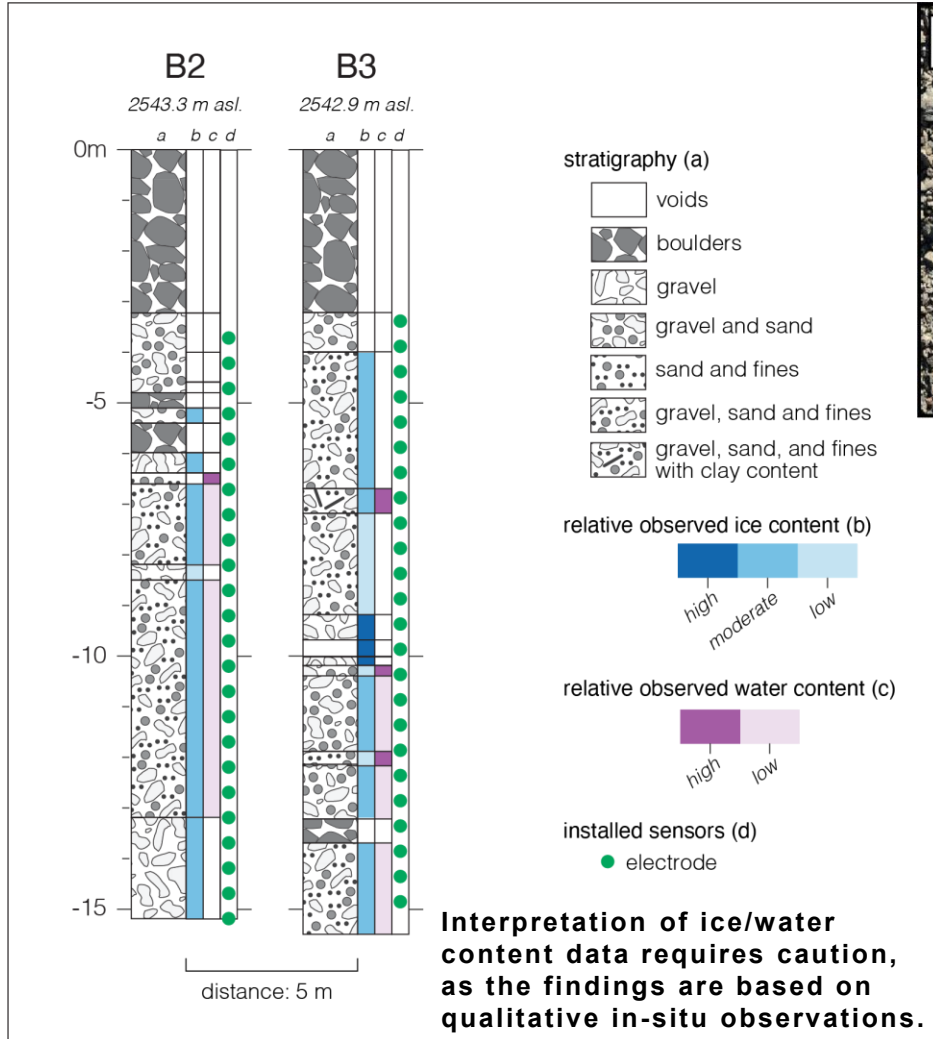

Aug. 2025
(During SIP data collection)

- **Active layer depth:** ~ 5 m
- **Permafrost:** ~ -0.1 °C, close to melting point

[Data from SLF (RoDynAlpS) & Permos (Swiss Permafrost Monitoring Network)]

Boreholes for SIP measurements

Borehole setup:

- Borehole depth: ~ 15 m
- Borehole distance: 5 m
- Electrode spacing: 0.5 m
- Electrodes per borehole: 24

SIP data collection

DAS-1 (field instrument)

- Dipole-Dipole sk-0 & sk-3 inline & cross-borehole
- Multiple-Gradient

→ Focus: Imaging

PSIP (lab instrument)

- Multiple-Gradient

→ Focus: Spectra over large frequency range

Contact resistances

Measured:

$$R_g = R_{c1} + R_{c2} + R_s$$

... along several electrode combinations

Estimation of contact resistances by least squares approach based on DAS-1 $V_{applied}/I_{applied}$ data assuming $R_s \ll R_{ci}$

Considers uncertainty of measured R_{AB} from **repeated current injections**

High contact resistances: might be underestimated or even above DAS-1 power capacity

Low contact resistances: values are highly reliable (validated with PSIP measurements)

Contact resistances

Comparison with contact resistances measured by PSIP

[Approach from Wang & Slater, 2019]

Estimation of contact resistances by least squares approach based on DAS-1 $V_{applied}/I_{applied}$ data assuming $R_s \ll R_{ci}$

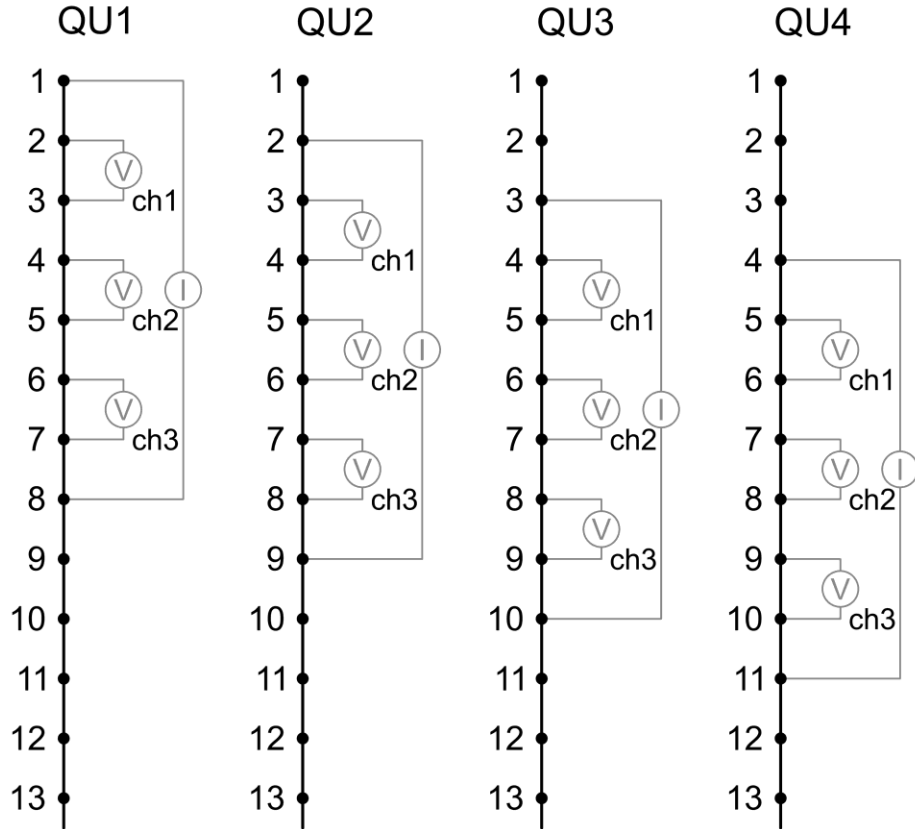

Considers uncertainty of measured R_{AB} from **repeated current injections**

High contact resistances: might be underestimated or even above DAS-1 power capacity

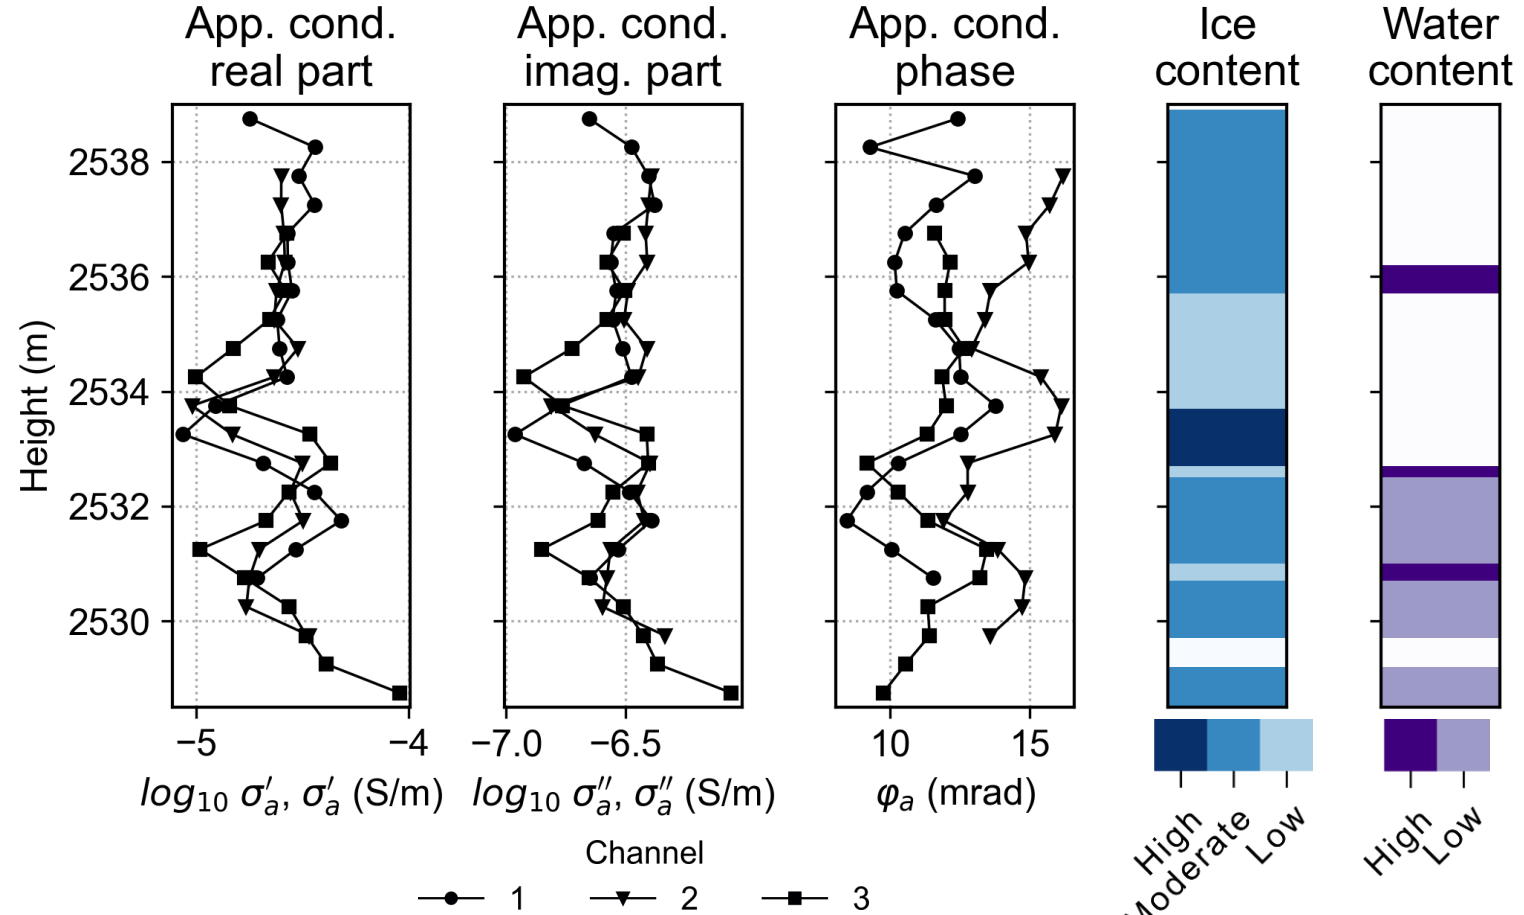

Low contact resistances: values are highly reliable (validated with PSIP measurements)

PSIP profiling

1.0 Hz

7.5 Hz

Numerical modeling dipole-dipole sk-0

Synthetic model

Pseudosections DD sk-0

Accumulation of positive impedance phase readings

Comparison: Field data pseudosections show a very similar pattern as the pseudosections of the modelled data

Numerical modeling dipole-dipole sk-3

Synthetic model

Pseudosections DD sk-3

Accumulation of positive impedance phase readings

Comparison: Field data pseudosections show a very similar pattern as the pseudosections of the modelled data

Inversion results

Dipole-dipole sk-3

Dipole-dipole sk-0

- Inversion after **keeping positive impedance phase readings**
- Results in **resistive and polarizable** (increased conductivity phase) **anomaly**
- Phase value **increase with increasing frequency**

Varying colorscale due to large difference in range of values

Conclusions experiment 3

- 1) **Large variations in conductivity magnitude and phase** along borehole in active rock glacier
- 2) Strong **negative IP effects** similar to tank experiment result from resistive and polarizable anomaly
- 3) **Resistive and polarizable anomaly** is correlated with maximum in ice content estimation

Overall conclusions

Experiments at different scales

(1) Borehole experiment

Meter scale

- **Lateral variations** in low-frequency **polarization** along borehole
- **Negative IP effects** due to resistive and polarizable anomaly

(2) Tank experiment

Decimeter scale

- **Similar negative IP effects** due to resistive and polarizable anomaly
- Allows to **validate polarization anomaly** with known geometry of the ice

(3) Rock samples experiment

Centimeter scale

- Effect in **thermal equilibrium** taking place in electric double layer
- Effect **during ice formation** due to charge separation
