<sup>5</sup> Florida A&M University – Florida State University, College of Engineering, Tallahassee, USA

This research has been funded in the framework of UNEP's International Methane Emissions Observatory (IMEO)

## Global South CH<sub>4</sub> emission measurements scarce / unsystematic → SWLF + WWTP measurement campaign (MET-CO)

- CH<sub>4</sub> short lifetime + low mitigation costs → near-term climate action
- Mitigation accounting / climate science ← accurate emission inventories
- Most EFs / model parameters derived from measurements in/at of developed countries conditions
- Global South CH<sub>4</sub> emission measurements scarce / unsystematic → large discrepancies among global databases and with national inventories (-60% to +180% for Colombia)
- Solid waste landfill (SWLF) CH<sub>4</sub> emissions fastest growing category in Colombia ← disposal in SWLF 43% (2009) to 98% (2020)
- UNEP's International Methane Emissions Observatory (IMEO) coordination/support → multi-sector observation-based baseline inventory for Colombia
- Conducted by Universidad Nacional de Colombia (UNAL, Bogota) and Carleton University (Ottawa, Canada) → MET-CO measurement campaign

## Instrument / methodology development + performance assessment

**In-house integrated, drone-borne ready CH<sub>4</sub> instrument** (< 2 kg; Internal battery powered; Based on an Axetris LGD Compact-A CH<sub>4</sub>)

**Performance in flight degraded very little once instrument was mech. locked**

**Floating chamber bubbling test**

**Direct (chamber) and indirect (sampling system) CH<sub>4</sub> conc. agreed within 2%**

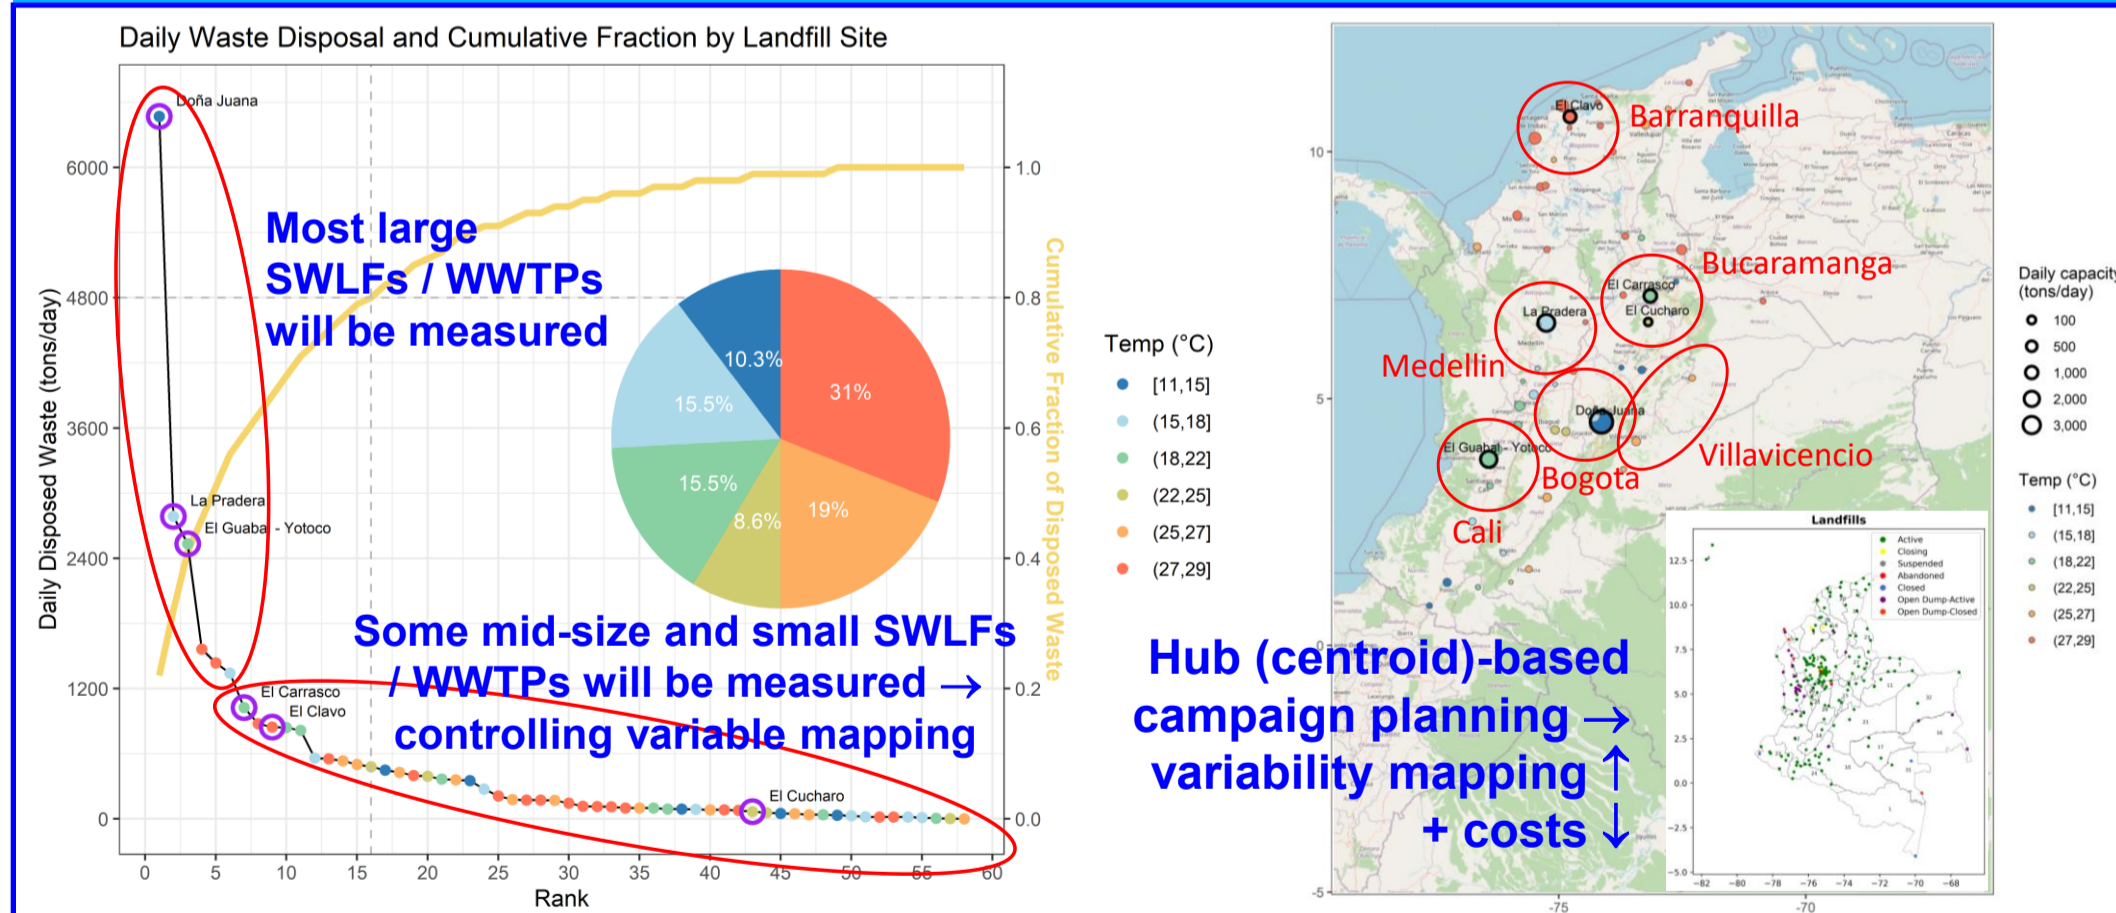

**Compost methane content increased with age** ← chamber desorption dynamics (t<sub>eq</sub> < 30 min)  
Compost fluxes difficult to measure using chambers

Ambient air precision better than 0.5 ppmv Hz<sup>-1/2</sup> → suitable for source proximity measurements

Allan variance (4790 ppmv CH<sub>4</sub> tank), 5 ppmv Hz<sup>-1/2</sup>, σ<sub>Allan</sub> ≈ 1 ppmv, τ ≈ 100 s

Cal. tank

## Observation-based inventory scale up / Measurement strategy / Hubs + facilities

- Facility by facility ("census-like") inventory → high granularity
- Mixed approach: large facilities directly measured + some mid- / small-size facilities → controlling variable mapping + emissions from non-measured facilities ← estimated from measurement-derived, categorized parameters
- Measurement strategy ← balance generated biogas = channeled + diffuse →
  - 1) Drone surface sniffing of active + closed SWLF cells + WWTP elevated units
  - 2) Soil / floating flux chambers / dissolved CH<sub>4</sub>
  - 3) Channeled biogas composition + flowrate
  - 4) Drone mass balance measurements (Carleton University)
  - 5) Biogas model tuning → mixed approach parameters

## First in situ measurements

**Small fluxes from cells closed ~10 yr ago (2.3; -1.3 mg CH<sub>4</sub> m<sup>-2</sup> day<sup>-1</sup>)**

**(Anomalous) wet month**

**Dry season**

**Collection well biogas accumulated flowrate**

**Poorly maintained lagoon system**

**Aerobic lagoon operating anaerobic → strong ebullition**

Dissolved methane (headspace) ≈ 6200 ppmv  
Enhancements near sources ≈ 0.3-17 ppmv

**Medium-size SWLF undergoing works to improve collection after meas. → will measure again**

**LARGE DIVERSITY IN WWTPs!**

**Better maintained / more complex WWTPs showed emission peaks near sewage entrance, digested sludge outlet and biofilter outlet**

Operator monitored collection well biogas composition / flowrate

Channeled biogas partition ← cell design / construction / operation

**Biogas burning effectiveness**

Low CH<sub>4</sub>, CO<sub>2</sub> + near-ambient O<sub>2</sub> levels associated with lowest flowrates → eventually extinguish combustion

**Found twofold increase in biogas generation wet month**

**Dry season → low flowrates (~70% wells) (compared to <20% during wet month)**

**Large flux from recently closed cell (0.15 kg CH<sub>4</sub> m<sup>-2</sup> day<sup>-1</sup>); Nearly zero from cell closed ~10 years ago**

Enhancements near sources ~3-17 ppmv; **Abandoned extraction pipeline = 39%**

Opportunity measurements

Methane uncorrelated with CO<sub>2</sub>

U(2 m) ≈ 1.6 m/s + Pasquill C

Active zone to road ≈ 650 m

**Fitted CH<sub>4</sub> emission = 738 kg/hr**

**IPCC estimation = 580 kg/hr**
